Heavins! what a spring was in his arm. Dryden. The soul is gathered within herself and recovers that spring which is weakened when she operates more in concert with the body.

Addison.

4. An elastic body, made of various materials, as a strip or wire of steel coiled spirally, a steel rod or plate, strips of steel suitably joined together, a mass or strip of indiarubber, &c., which, when bent or forced from its natural state, has the power of recovering it again in virtue of its elasticity. Springs are used for various purposes—diminishing concussion, as in carriages; for motive power, acting through the tendency of a metallic coil to unwind itself, as in clocks and watches; or to communicate motion by sudden release from a state of tension, as the bow to the arrow, the spring of a gun-lock, &c.; others are employed to measure weight and other force, 4. An elastic body, made of various materials,

as in the spring-balance, as regulators to control the movement of wheel-works, &c. 5. Any active power; that by which action or motion is produced or propagated.

Our author shuns by vulgar springs to move The hero's glory.

These are the daily causes of war and springs of negotiation with absolute princes.

Brougham.

6. A natural fountain of water; an issue of water from the earth, or the basin of water at the place of its issue. Springs have their origin in the water which falls upon the earth, origin the water which anisupon the earth, and sinks through porous soils till it arrives at a stratum impervious to water, where it forms subterranean reservoirs at various depths. When confined in this manner it is subject to the pressure of the water which fills the channels through which it has defills the channels through which it has defills the channels through which it has descended, and when this pressure is sufficient to overcome the resistance of the superincumbent mass of earth the water breaks through the superficial strata, and gushes forth in a spring. In descending downwards and rising upwards through various mineral masses the water of springs becomes impregnated with gaseous, saline, earthy, or metallic admixtures, as carbonic acid gas, sulphuretted bytogen gas, nitrogen carbonate of It admixtures, as carbonic acid gas, sulphuretted hydrogen gas, nitrogen, carbonate of lime, silica, carbonate of iron, &c. When these substances are present in considerable quantity the springs become what are known as mineral springs, acquiring the peculiar properties which give them their medicinal value. Warm and hot springs are common, especially in volcanic countries, where they are sometimes distinguished by where they are sometimes distinguished by violent ebullitions. (See GEYSER.) As a general rule springs are permanent in proportion to the depth to which the water which supplies them has descended from the curron. Some carriers we see the the surface. Some springs run for a time and then stop altogether, and after a time run again, and again stop; these are called intermittent springs. (See under INTERMITTENT) Others do not cease to flow but only discharge a much smaller quantity of water for a certain time, and then give out a greater quantity; these are called variable or reciprocating springs.

His steeds to water at those springs On chaliced flowers that lies. Shak. Used adjectively.

He bathed himself in cold spring water in the midst of winter.

most of winter.

7. Any source of supply; that from which supplies are drawn; as, the real Christian has in his own breast a perpetual and inexhaustible spring of joy. 'The sacred spring whence right and honour stream.' Sir J. Davies.—8. One of the four seasons of the Danies.—8. One of the four seasons of the year; the season in which plants begin to vegetate and rise; the vernal season. For the northern hemisphere the spring season commences when the sun enters Aries, or about the 21st of March, and ends at the time of the summer solstice, or about the 22d of June. In common language, spring commences in February or March and ends in April or May. Hence—9. The early part; the first and freshest part of any state or time; as, the spring of one's life. Standard (stand'ard),n. (From O. Fr. estandart, estendart, Mod. Fr. étendard, It. stendardo, Sp. estandarte, Pr. estandart, these forms, according to Littré, being from the Teutonic verb to stand, the old standard being a pole or mast set up during a battle; according to Diez, Brachet, &c., from L. extendere, to extend, to spread out, to display. There is no doubt that in the Teutonic languages the word was looked upon as connected with stand, and several of the meanings in English (as 6 and 8 below) have arisen in this way. Comp. also D. standard, M. H. G. standart, Mod. G. standard.) I. In its widest sense, a flag or ensign round which

men rally, or under which they unite for a common purpose; a flag or carved symbolical figure, &c., erected on a long pole or staff, serving as a rallying-point or the like. In a more strict sense the term is applied to a flag which bears the arms, device, or motto of the owner, long in proportion to its depth, tapering towards the fly, and, except when belonging to princes of the bloodroyal, slit at the end. The so-called British royal standard is more correctly a banner, being a square flag, and having its whole field covered solely by the national arms. The cavalry standards are also, properly speaking, banners, and are of small size, of a colour corresponding to the regimental facings, and charged with the cipher, number, insignia, and honours of the regiment. The infantry corresponding flags are called colours.—2. Star (stär), n. [A word common to all the Indo-European languages. A. Sax. steorra, Sc. starn, Icel. stjarna, Goth. stairno, D. ster, O.D. sterne, G. stern; cog. L. stella (for sterula, also astrum), Gr. aster, Armor. and Corn. steren, Per. satarah, Skr. tåra (for stara), Vedic Skr. stri, pl. staras—star. Probably from root of E. strew, Skr. stri, to strew, from the heavenly bodies scattering or aprinkling light 1. In a popular sense, any sprinkling light.] 1. In a popular sense, any celestial body whatever except the sun and moon; but, in astron. the term is usually restricted to one of those self-shining bodies constituted like the sun, situated at immense distances from us, and doubtless, like our sun, the centres of systems similar to our own. Stars are distinguished from planets by remaining apparently immovable with respect to one another, and hence they were called fixed stars, although their fixty has been disproved in numerous cases, and is no longer believed in regard to any. The prinlonger believed in regard to any. The principal points which form the subjects of astronomical inquiries regarding the stars are their apparent and relative magnitudes, their distribution, their number, their distances, motions, and nature. In order to distinguish the stars one from another the ancients divided the heavens into different spaces called vided the heavens into different spaces called constellations, which they supposed to be occupied by the figures of animals and other objects, as a lion, a bear, a man, a lyre, &c. (See CONSTELLATION.) The stars are divided, according to their brightness, into stars of the first, second, third, &c., magnitudes; but no magnitude, in the proper sense of the word, has yet been observed in any star. All the stars beyond the sixth or seventh magnitude are called telescopic stars, as they cannot be seen without the aid of the telescope. The gradations of magnitude among the telescopic stars are continued by astronomers from the eighth down to the sixteenth. from the eighth down to the sixteenth. The stars are very irregularly distributed over the celestial sphere. In some regions scarcely a star is to be seen, while in others they seem crowded together, especially in the Milky Way, where they appear, when viewed through a powerful telescope, to be crowded almost beyond imagination. Of the sters yields to the naked are at anyone time. stars visible to the naked eye at any one time the number probably does not exceed a few thousands, but in the telescope their number is so great as to defy all calculation; and, besides, there is every reason to believe that there are countless hosts which lie beyond there are countiess hosts which lie beyond the reach of the most powerful telescopes. The distances of the fixed stars from the earth are very great. The nearest yet found, that of a Centauri, a double star in the southern hemisphere, being calculated at 20 billions of miles, so that light takes 3½ years to travel from it to our earth. Many stars have been observed whose light appears to undergo a regular periodic increase and diminution of brightness empurities of thickness. tion of brightness, amounting, in some in-stances, to a complete extinction and revival. These are called variable and periodic stars. It is found that some stars, formerly distin-guished by their splendour, have entirely disappeared, others have shone forth with extraordinary brilliancy, and, after a longer extraordinary brilliancy, and, after a longer or shorter period, have gradually died away and become extinct. These are called temporary stars. Many of the stars are found, when observed with telescopes of high magnifying power, to be composed of two, and some of them of three or more stars in close juxtaposition. These are termed double and multiple stars. The expectances known as Juxtaposition. These are termed acuse and multiple stars. The appearances known as nebulæ are, in many cases at least, agglomerations of stars, separated from our system and from one another by unfathomable starless intervals. Steam (stem), n. [A. Sax stem, steam, steam, spour, smoke; D stoom, Fris. stoame, steam; L.G. stüm, drift of snow or rain. Perhaps from a root stam, signifying dark, seen without the s in Skr. tamas, darkness, timira, dark.] 1. The vaporous substance into which water is converted under certain circumstances of heat and pressure; water into which water is converted under certain circumstances of heat and pressure; water in a gaseous state. Water gives off vapour or steam at every temperature—a low tem-perature not preventing the formation of steam, but only decreasing its density. The term, however, is strictly applied to the elastic aeriform fluid generated by heating water to the boiling-point. When water elastic aeritorm muit generated by nearing water to the boiling-point. When water in an open vessel is heated to the temperature of 212 Fr., or to the boiling-point, globules of steam are formed at the bottom, and rise to the surface; and the continued application of heat, even though increased indefinitely, will only cause a more copious and rapid formation of steam, and will find the surface of the water with the continued and the surface of the water with and rapid formation of steam, and will fin-ally evaporate the whole of the water with-out raising the temperature of either. In this case all the heat which enters into the water is solely employed in converting it into steam of the temperature of boiling water. But if the water be confined in a strong close vessel, both it and the steam which it produces may be brought to any

temperature; and as steam at 212 occupies nearly 1700 times the space of the water from which it is generated, it follows that, when thus confined, it must exercise an enormous elastic or expansive force, which may also be shown to be proportional to its temperature. Steam which has received additional heat apart from water is called superheated steam, and approximates to the condition of a perfect gas. Steam, however, as used in the steam-engine holds water in suspension mechanically, and differs sensibly from the condition of a perfect gas. It is called saturated or net steam. When sibly from the condition of a perfect gas. It is called saturated or vet steam. When the temperature of saturated steam is considerably above 212° F. the steam formed under such circumstances is termed high-pressure steam; at 212° F. it is termed low-pressure steam, and its pressure is equal to that of one atmosphere, or 14°7 lbs. on the square inch. Steam in its perfect state is transparent, colourless, and invisible; but when it has been deprived of part of its with the square inch. Steam in its perfect state is transparent, colourless, and invisible; but when it has been deprived of part of its heat by coming into contact with cold air, it suddenly assumes a cloudy appearance, and is condensed into water. Hence appears another important property of steam, its condensibility; so that whenever cold is applied to it it suddenly returns to the liquid state, and thus can be employed to produce a vacuum. From the properties above briefly adverted to, steam constitutes an invaluable agent for the production of mechanical force, as exemplified in the vast and multiplied uses of the steam-engine. Steam is also employed as an agent in distributing the heat used for warming buildings, in heating baths, evaporating solutions, distilling, brewing, drying, dyeing, and even for cookery.—2. In popular usage, the visible moist vapour which rises from water, and from all moist and liquid bodies, when subjected to the action of heat; as, the steam of boiling water, of malt, of a tanbed, &c. Steam-casing (stem'kis-ing), n. A vacuity surrounding any vessel, pipe, &c., into which steam may be admitted, in order to prevent the loss of heat by radiation; a steam-jacket. Steam-chamber (stem'chim-ber), n. A division or compartment in the boller of a steam-engine above the water, whence steam is conducted to the engine. Called also Steam-room and Steam-doms.

Steam-chest (stem'chest), n. 1. A box or chamber above a steam-boiler to form a

reservoir for the steam, and from whence it reservoir for the steam, and from whence it passes to the engine; in locomotive engines, a box attached to the cylinders, into which the steam is admitted by the regulator. The slide-valve works in this box over the steam-ports, which open into it from the cylinder.—2. In cation-printing, a form of steam apparatus in which steam is applied to cloth in order to fix the colours.—3. A chamber heated by steam, and used for softening timber which is to be bent to a curved form as shins' nlawking. Called also curved form, as ships' planking. Called also a Steamer

Steam - chimney (stem chim-ni), n. An annular chamber around the chimney of a boiler-furnace for superheating steam.

provements from the hands of Newcomen, Beighton, Blakey, and others. Still, however, it was imperfect and rude in its construction, and was chiefly applied to the draining of mines or the raising of water. Up to this time it was properly an atmospheric engine, as the actual moving power was the pressure of the atmosphere, the steam only producing a vacuum under the piston. The steam-engine was brought to a high state of perfection by the celebrated James Watt about the year 1782. The numerous and vital improvements introduced by him, both in the combination of its meby him, both in the combination of its me-chanism and in the economy of its management, have rendered the steam-engine at once the most powerful, the most easily ap-plied and regulated, and generally speaking the least expensive of all prime movers for impelling machinery of every description.

Steam-engine (stêm'en-jin), n. An engine worked by steam, or an engine in which the mechanical force arising from the elasticity and expansive action of steam, or ticity and expansive action of steam, or from its property of rapid condensation, or from the combination of these principles, is made available as a source of motive power in the arts and manufactures, and in locomotion. The invention of the steam-engine has been ascribed by the English to the Marquis of Worcester, who published an account of it about the middle of the seventeenth century. By the French the invention has been ascribed to Papin towards the close of the same century. Papin's plan contained the earliest suggestion of a vacuum under a piston by the agency of steam. The first actual working steam-engine of which there is any record was invented and constructed by Captain Savery, an Englishman, to whom a patent was granted for it constructed by Captesin was granted for it in 1668. This engine was employed to raise water by the expansion and condensation of steam. The steam-engine received great im-

Steam-engines vary much in magnitude, form, and proportions, as well as in the details of the machinery by which the power of the steam is applied, but all work upon substantially the same principles which were embodied in Watt's steam-engine, and to understand one is to understand all. The batts. Ultrathion represents a sections substantially the same principles which were embodied in Watt's steam-engine, and to understand one is to understand all. The above illustration represents a sectional elevation of a Condensing Steam-engine. The construction and action of the steamengine will be readily understood from this illustration. The pipe which conveys the steam from the boiler opens into the part marked l, which incloses a movable valve by means of which the steam may be alternately admitted into the cylinder a by the upper port c and lower a; between these points the piston b works steam-tight. The valve l is so contrived that while it allows steam to pass into the cylinder through one of the ports, it shall at the same time open a communication between the opposite side of the piston and the condenser n, which is a hollow vessel kept constantly immersed incoid water, a portion of which is admitted into it by the injection-cock v; consequently, the steam thus admitted is instantly deprived of its heat, and reconverted into its original form of water, thereby forming a vacuum. Thus it will be seen that, on the communication being opened up between the boiler and either side of the piston, the latter will ascend or descend in the cylinder unimpeded by the resistance of the steam; and as the motions of the steam-valve l are regulated by the engine itself, the above action is kept up continuously. The alternating rectilinear motion thus generated within the cylinder is transmited. ted, by means of a rod attached to the piston, to a strong beam ff, movable upon a central axis, a system of jointed rods ee, called the parallel motion, being interposed for the purpose of neutralizing the disturbing action which the circular path of the beam would otherwise exert upon the piston. The reciprocating motion of the beam is now, through the intervention of the connecting-rod g and crank h, converted into a circular or rotatory motion, which is rendered continuous and uniform by the flywheel i, to the axis of which the machinery to be impelled is connected. The air-pump g for withdrawing the vapour and water from the condenser, the feed-pump s for supplying the boilers, and cold-water pump t for supplying the condenser cistern, are all worked by rods from the beam; and the governor u. for maintaining uniformity of motion, is driven by a band from the crankshaft. The above description refers more immediately to that class of steam-engines called low-pressure or condensing engines, in which the power derived from the ranid ted, by means of a rod attached to the piscalled low-pressure or condensing engines, in which the power derived from the rapid condensation of the steam is made available in combination with that due to its elasticity; but if we suppose the condensing apparatus removed, and the waste steam allowed to escape into the atmosphere, it will then be equally applicable to that kind then be equally applicable to that kind called high-pressure or non-condensing engines, which employ the elastic action of the steam alone. Steam-engines are classified in various ways, as portable, marine, locomotive, pumping, blowing, winding, &c. According to the arrangement of the chief parts they are classed as beam, oscillating-vitinder, horizontal, vertical, &c. The mechanical energy of a steam-engine is usually estimated in horse-power. See Horse-Power. POWER.

Steamer (stëm'er), n. 1. A vessel propelled by steam; a steam-ship.—2. A fire-engine the pumps of which are worked by steam. 3. A vessel in which articles are subjected to the action of steam, as in washing or cookery. See STEAM-CHEST.—4. In paper, making, a vessel in which old paper, fibre, &c., is treated in order to soften it.—5. An apparatus for steaming grain preparatory to grinding.—6. A locomotive for roads. See ROAD-STEAMER.

Rteam_gas (stëm'gas), n. Same as Super-heated Steam. See under STEAM.

Steam_gauge (stëm'gā), n. An attachment to a boiler to indicate the pressure of steam; a pressure-gauge. There are many forms. One of the older is a bent tube partially filled with mercury, one end of which springs from the boiler, so that the steam raises the mercury exceeding to the smount of pressure according to the smount of the s from the boiler, so that the steam raises the mercury according to the amount of pressure. A very common form of gauge is that known as Bourdon's, which consists essentially of a flattened metal tube, closed at one end and bent circularly, into which the steam is admitted. As such a tube tends to straighten itself out by the force of the steam the amount of pressure can assily be steam the amount of pressure can easily be ascertained by an attached index apparatus. **Steam - governor** (stēm'gu-vērn-ēr). Governor.

Steam-gun (stem'gun), n. A gun the projectile force of which is derived from the expansion of steam issuing through a shotted tube.

Steam-hammer (stěm'ham-èr), n. A form of heavy forge hammer operated by steam, consisting usually of a steam cylinder and piston, with metal striker attached, placed vertically over the anvil. There are two principal varieties: in one the cylinder is fixed, and the hammer is attached to the piston rod and is oversted by the diverse. fixed, and the hammer is attached to the piston-rod, and is operated by the direct action of the steam in the cylinder; in the other the piston is fixed, and the hammer is attached to the lower end of the cylinder, which similarly rises and falls by the action of the steam in the cylinder. The former is known as Nasmyth's, and the latter as Condie's hammer, which is shown in the cut attached. In the entablature of the figure is a steam and exhaust valve, and attached to it a hollow piston-rod, acting as steam and exhaust pipe, to which the piston is attached as a fixture. The steam, being introduced into the cylinder or hammer immediately above the piston, presses the cylinder cover, and raises the hammer between the guides to the required height. The steam being then cut off, and the exhaust-valve opened,

the hammer falls, not only with the velocity of gravity, but with the additional velocity produced by the compression of the air under the piston during the latter portion of the hammer's ascent, which, acting as a recoil, adds considerably to the effect of the blow. With the most powerful ham-mers steam is also introduced on the under side of the pictor as contract water that side of the piston, so as to augment still further the speed and force of the blow. The valves and valve-gearing are so arranged that the person in charge of the machine can arrest the motion of the hammer while falling, or cause it to fall at any moment stills. while ascending. In Ramsbottom's ham-mer two hammer cylinders move horizonmer two hammer cylinders move horizontally in the same line, but in opposite directions, and the piece to be forged is placed between the two. There are some other kinds of steam-hammers suitable for light work, in most of which the hammer-head is attached to the end of a horizontal shaft which acts as a lever, the fulcrum of which is nearer the free end of the shaft than the end bearing the hammer. The hammer is raised by cams attached to a revolving drum, and falls when by the revolution of the drum the shaft is freed from one of the cams. These are often called Steam-title.

Steam-kitchem (stěm'kich-en), n. An apparatus for cooking by steam.

Steam-launch (stěm'länsh), n. A large kind of boat propelled by steam.

Steam-navigation (stěm'nav-i-gā-shon), n. The art of applying the power of steam to the propulsion of boats and vessels; the art of navigating steam-vessels; steam's applying the property of the propulsion of boats and vessels; the art of navigating steam-vessels; steam's applying the property of the pro

of navigating steam-vessels.

Steam-packet (stem'pak-et), n. A packet or vessel propelled by steam, and running periodically between certain ports.

Steam-pipe (stem'pip), n. Any pipe used for conveying steam from a boiler to a steam-engine, or through a workshop for the purpose of heating, or for any other purpose.

Steam - plough (stem'plou), n. A plough or gang of ploughs worked by a steam-engine instead of horses.

instead of horses. **Steam port** (stëm'port), n. In locomotive engines, the name given to two oblong passages from the steam-chest to the inside of the cylinder, by which the steam enters and returns, above and below the piston. Known as the induction port or the eduction port respectively, according to the course of the steam o steam

Steam-power (stěm'pou-ér), n. of steam applied to move machinery or produce any results.

Steam - press (stem pres), n. A press actuated by steam power acting directly or intermediately; specifically, a printing-press worked by steam

Steam - winch (stēm'winsh), n. A form of winch or hoisting apparatus in which rotatory motion is imparted to the winding axle from the piston-rod of a steam-engine, directly, or indirectly by means of bevel-gearing, the direct action giving most rapidity, the indirect most power.

Steamy (stēm'i), a. Consisting of or abounding in steam; resembling steam; vaporous; misty.

Stean (stên), n. and v. See STEEN.

Stearate (ste'a-rat), n. A salt of stearic acid. The neutral stearates of the alkalies

acid. The neutral stearates of the alkalies are perfect soaps.

Stearic stearies, a. Of, pertaining to, or obtained from stearine.—Stearic acid (C₁₈ H₈₀C₉), a monobasic acid, perhaps the most important and most abundant of the fatty acids. It exists in combination with gly-cerine, as stearine, in beef and mutton fat, and in several vegetable fats, such as the butter of cacao. It is obtained from stearbutter of cacao. It is obtained from stearine by saponification, and also from mutton
suet by a similar process. Stearic acid is
in the form of brilliant white scaly crystals;
it is inodorous, tasteless, insoluble in water,
but soluble in alcohol and ether. It burns
like wax, and is used in the formation of
candles. It forms compounds with the
alkalies, earths, and metallic oxides, which
are called stearates. are called stearates.

Stearine, Stearin (stë'a-rin), n. [Gr. stear, suct.] ($\mathbb{C}_{2} \mathbb{H}_{10} \mathbb{O}_{2}$). 1. The chief ingredient of suct and tallow, or the harder ingredient of suct and tallow, or the harder ingredient of suct and tallow, or the harder ingredient is obtained from mutton suct by repeated solution in ether and crystallization. It may also be obtained by pressing tallow between hot plates, and afterwards dissolving in hot ether, which on cooling deposits the stearine. It has a pearly lustre, is soft to the touch, but not greasy. It is insoluble in water, but soluble in hot alcohol and ether. When treated with superheated steam it is separated into stearic acid and glycerine, and when boiled with alkalies is seponified, that is, the stearic acid combines with the alkali, forming soap, and glycerine is separated. When melted it resembles

war. There are three stearines, which may be all regarded as derivatives of glycerine in which one, two, or three O H groups are replaced by the radical stearyl. Natural stearine is the tristearyl derivative of glycerine. 2. A popular name for stearie acid as used in making candles. Stearinery (stear-in-ér-i), n. The process of making stearine from animal or vegetable

fats; the manufacture of stearine or stearine

Stearyl (stě'ar-il), n. (C₁₈H₃₅O.) The radical of stearic acid.

Gr. stear, steatos, fat, tallow.] Soapstone, so called from its smooth or unctuous feel; so called from its smooth of unctuous teel, a sub-species of rhomboidal mica. It is of two kinds, the common and the pagodite or lardstone. It is sometimes confounded with talc, to which it is allied. It is a compact stone, white, green of all shades, gray, brown or marbled, and sometimes herborted by black deadlines. It is found in many thanks and the stand of the s ized by black dendrites. It is found in me-talliferous veins, with the ores of copper, lead, zinc, silver, and tin. It is a hydrated silicate of magnesia and alumina. It is used in the manufacture of porcelain, in polishing marble, &c.; as the basis of rouge and other cosmetic powders; in the composition

of crayons, &c.

Steatitic (ste-a-tit'ik), a. Pertaining to steatite or soapstone; of the nature of steatite or resembling it.

Steatocele (stë-at'ë-sël), n. [Gr. stear, fat, këlë, a tumour.] A tumour of the scrotum, containing fat.

Steek, Steik (stěk), v.t. [A Scotch word; A. Sax. stician, to pierce, to stick, to stick in. See STICK, STITCH.] 1. To pierce with a sharp-pointed instrument; to stitch or sew with a needle.—2. To close or shut; as, to steek a door.

to steek a door.

Steek Stelk (stêk), n. The act of stitching with a needle, a stitch. [Scotch.]

Steel (stêl), n. [A. Sax. stel, L. G. D. and Dan. staal, Icel. stal, G. staht, O.G. stahal. Wachstate, teel state, et. state, o.g. state. Wachter and Adelung connect the word with G. stachel, a prick, from stechen, to stick, to prick, on type of Fr. acter, steel, from L. actes, a point, an edge. 1 1. Iron combined with a small portion of carbon. Steel usually contains also small quantities of silially contains also small quantities of sili-con, phosphorus, manganese, and sulphur, but iron and carbon appear to be its only essential constituents. The relative pro-portions of iron and carbon vary in steel of different qualities; but in that used for ordinary purposes the carbon amounts from about 0.5 to 1.5 per cent, the tough-ness, tenacity, and hardness increasing with the increase of the carbon, the elasticity di-minishing as the hardness increases, and vice serses. At a red heat steel is malleable and may be welded. The colour is a bright grayish white, the texture closely granular, grayish white, the texture closely granular, the specific gravity varying from 7°52 to 7°81. Steel formed from ber-iron by cementation is called blistered steel, from its surface ac-

quiring a bistered character in the process. (See CEMENTATION.) When blistered steel is rolled or beaten down into bars, it is called shear-steel, and if it be melted, cast into ingots, and again rolled out into bars, it forms cost-steel. Cast-steel is now largely it forms cast-steel. Cast-steel is now largely manufactured by what is known as Bessemer's process. (See BESSEMER'S PROCESS.) Natural or German steel is an impure and variable kind of steel procured from cast-iron, or obtained at once from the ore. The natural steel yielded by cast-iron, manufactured in the refining houses, is known by the general name of furnace steel, and that which has only been once treated with a refining furnace is particularly called rough steel. The peculiarity of steel, upon which its high value in the arts in a great measure depends, is its property of becoming hard after being heated to redness and then sud-denly cooled by being plunged into cold water, and of being again softened down to any requisite degree by the application of a certain temperature. This process is called tempering. It is found that the higher the temperature to which steel is raised, and the more audden the cooling, the greater is the hardness; and hence, any degree of hard-ness can be given to steel which is required for the various purposes to which it plied. According to the degree of hardness to which steel is tempered it assumes various colours, and formerly these colours served as guides to the workman. Now, however, a thermometer, with a bath of mercury or oil, is employed, and the operamercury or oil, is employed, and the opera-tion of tempering is performed with a much greater degree of certainty. The uses of steel in forming various kinds of instru-ments, edge-tools, springs, &c., are well known.—Indian steel. See WOOTZ.—2. The principal hody of a tree, shrub, or plant of any kind; the firm part which supports the branches; the ascending axis, which grows in an opposite direction to the root or descending axis; the stalk. The stem is composed of fibrous, spiral, and cellular tissues, arranged in various ways, mostly assuming a cylindrical form and having a perpendicular direction, and bearing upon it the various parts of the plant. Its form and direction, however, are subject to much variation in particular cases. In regard to internal structure there are three principal modifications of stems characteristic of the three great natural classes into

which the vegetable kingdom is divided. namely, exogens, endogens, and acrogens, stems are herbaceous or woody, solid or hollow, jointed or unjointed, branched or simple. Sometimes they are so weak as to simple. Sometimes they are so weak as to be procumbent, although more generally firm and erect; sometimes weak stems are twining, or are upheld in various ways by the climbing habit of the plant. In some plants the stem is so short as to seem to be wanting, the leaves and flower-talks appearing to spring from the top of the root. There wanting, the leaves and nower-staiks appear-ing to spring from the top of the root. -Ster. A termination as in maltster, game-

ster, spinster, songster, denoting occupation. In the earliest times, and up to about the end of the thirteenth century, it was geneend of the thirteenth century, it was generally the sign of the feminine gender, corresponding to the masculine -ere or -er. In the fourteenth century it began to give place as a feminine termination to the Norman -ess. In modern literary English there is now only one feminine word with this suffix, viz. spinster, but huckster was used very late as a feminine; and in Scotch and provincial English seveter is still used. When the suffix ster was felt to longer to merk vincial English secosies is sent used. When the suffix-ster was felt no longer to mark the feminine distinctively, some new femi-nines were formed by the addition of the termination -ess to the -ster, as songstress and seamstress.

The suffix -ster now often marks the agent wire more or less a sense of contempt and depreciation as punster, trickster, gamester.

Dr. Morris.

more or less a sense of contemps and spinster, trickter, gamester.

But we cannot recognize the termination ster as being, or as having been at some time past, a feminine formative in every instance. Not only does the present use of such old words as Baxter, huckster, mattiter, songster, Webster, not to urge the more recent oldster, youngster, roadster, make it hard to prove them all feminines; but even if we push our inquiries further back we nowhere find the group clearly defined as such except in modern Dutch. There was in Anglo-Saxon bacers and bactistre, and yet Pharaoh's baker in Genesis xi. is bactistre. Grimm conjectured that these nouns in settre are all that is left of an older pair of declensions, whereof one was masculine in strate, the other feminine in strate.

Stereomonoscope (ster'ē-ō-mon"o-skōp), n. [Gr. stereos, solid, monos, alone, single, and skopeō, to see.] An instrument with two lenses for exhibiting on a screen of ground glass a single picture so as to give it all the effect of solidity.

Stereopticon (ster-ē-op'ti-kon), n. [Gr. stereos, solid, and optikon, relating to sight.] An instrument, consisting of a sort of double magic lantern, for exhibiting photographic pictures greatly magnified upon a wall or screen with stereoscopic effect.

Stereoscope (ster'ē-ō-skōp), n. [Gr. stereos, solid, and skopeō, to view.] An optical instrument to illustrate the phenomena of binocular vision. An object viewed by both eyes does not appear to each under the same angle; hence whatever we look upon is apprehended with senses of fritien through the send to the sense of fritien through the send the sense of fritien through hence whatever we look upon is apprehended by the sense of vision through the medium of by the sense of vision through the medium of two distinct images which unite in the sen-sorium of the brain and give us the idea of substance and solidity. The stereoscope is an optical apparatus which enables us to look upon two pictures taken under a small differ-ence of angular view, each eye looking upon one picture only; and thus, as in ordinary vision, two images are conveyed to the brain which unite into one, exhibiting the objects represented under a high degree of relief. A reflecting form of stereoscope was invented A reflecting form of stereoscope was invented

by Sir C. Wheatstone in 1888. It is so constructed that the two pictures are reflected to the eyes from two small plane mirrors placed at right angles the faces being towards the observer. Subsequently Sir D. Brewster invented the lenticular or refracting stereoscope, based on the refractive properties of

semi-double convex lenses. This is the one now in general use. There are many forms of it, one of which is shown in the figure. a are tubes containing the two halves of a lens; b is a glass slide on which the two views are depicted by the photographic process; cis a flap, covered with a light-coloured paper to receive the light and reflect it upon the slide, the lid on the top admitting light when the pictures are opaque. When the tubes a are adjusted to suit the eye the observer takes the one picture into the right ave and the other

adjusted to suit the eye the observer takes the one picture into the right eye and the other into the left eye, but the perceptive faculty apprehends only one image, and that in bold substantial relief and intensity.

Stereoscopic, Stereoscopical (ster'8-8-skop'ik, ster'8-8-skop'ik, al), a. Pertaining to the stereoscope; adapted to the stereoscope; produced by the stereoscope; as, stereoscopic pictures; stereoscopic views.

Stereotomic, Stereotomical (ster'ē-ō-tom'ik, ster'ē-ō-tom'ik-al), a. Pertaining to or performed by stereotomy.

Stereotomy (ster-ē-ot'o-mi), n. [Gr. stereos, fixed, and tomē, a cutting, from temnō, to cut.] The science or art of cutting solids into certain figures or sections.

Stereotrope (sterê-ô-trôp), n. [Gr. stereos, solid, and tropē, a turning, from trepē, to turn.] An instrument by which an object is perceived as if in motion and with an appearance of solidity or relief as in nature. It consists of a series of stereoscopic pictures, teconsists of a series of stereoscopic pictures, generally eight, of an object in the successive positions it assumes in completing any motion, affixed to an octagonal drum revolving under an ordinary lenticular stereoscope, and viewed through a solid cylinder pierced in its entire length by two apertures, which makes four revolutions for one of the picture-drum. The observer thus sees the object constantly in one place, but its parts apparently in motion and in solid and natural relief.

Stereotype (ster'ē-ō-tip), n. [Gr. stereos, fixed, and typos, type, form.] I. Lit. fixed metal type; hence, a plate cast from a stucco or papier-maché mould, on which is a facsimile of the superficies of arranged types, which plate being fitted to a block may be

which plate being fitted to a block may be used under the press exactly as movable types are used, and being retained may serve at any time to throw off an additional imat any time to throw off an additional impression. The plates are composed of an alloy similar to ordinary type-metal. The original process, invented by Mr. William Ged, a goldsmith of Edinburgh, consisted in taking a stucco cast of a form of type, which, after being subjected to a gradual baking, was used as a mould to obtain the fac-similer of the form of type. This process has been taking a stuccocast of a form of type, which, after being subjected to a gradual baking, was used as a mould to obtain the fac-simile of the form of type. This process has been greatly supplanted by what is known as the papier-mache process. This generally consists in covering the form, the face of which is oiled, with a soft, moist matrix of several sheets of tissue, blotting, and brown paper, stuck together by a mixture of glue, paste, and powdered French chalk, the tissue paper being next the type. A wet linen cloth is laid over the paper, and the matrix is dabbed by a beating-brush so as to drive the soft paper into all the interstices between the letters of the form. The hollows which now appear in the back are filled up by a smooth coat of stucce; and the matrix, after being backed up by a sheet of strong paper, is next subjected to a heavy pressure over a steam-chest and thoroughly dried while still connected with the type. It is then removed and placed in a casting-box, into which molten metal is poured, so as to produce from the matrix a plate with the type in relief. When the metal is set the mould is opened, the matrix removed, and the plate form the segment of a circle to enable the plate form the segment of a circle to enable the plate form the segment of a circle to enable the plate to fit on to the impression cylinder. For printing the finer class of illustrated books, &c., plates are produced by the process of electrotyping. See Electrotyptpe.

Stoic (sto'ik), n. [Gr. Stōikos, from Stoa, a porch in Athens where the philosopher Zeno taught.] 1. A disciple of the philosopher Zeno, who founded a sect about 508 B.C. He taught that men should be free from passaged. taught that men should be free from passion, unmoved by joy or grief, and submit without complaint to the unavoidable necessity by which all things are governed. The Stoics are proverbially known for the sternness and austerity of their ethical doctrines, and for the influence which their teneta exercised over some of the noblest spirits of antiquity, especially among the Romans. Their system appears to have been an attempt to reconcile a theological panthesism and a materialist psychology with a logic which seeks the foundations of knowledge in the representations or percentions logic which seeks the foundations of know-ledge in the representations or perceptions of the senses, and a morality which claims as its first principle the absolute freedom of the human will. The Stoics teach that whatever is real is material; matter and force are the two ultimate principles; mat-ter is of itself motionless and unformed, though caughle of receiving all potions and the the two intimate principles; mater is of itself motionless and unformed, though capable of receiving all motions and all forms. Force is the active, moving, and moulding principle, and is inseparably joined with matter; the working force in the universe is God, whose existence as a wise thinking being is proved by the beauty and adaptation of the world. The supreme end of life, or the highest good, is virtue, that is, a life conformed to nature, the agreement of human conduct with the all-controlling law of nature, or of the human with the divine will; not contemplation, but action, is the supreme problem for man; virtue is sufficient for happiness, but happiness or pleasure should never be made the end of human endeavour. The wise man alone attains to the complete performance of his duty; he is without passion, although not without feeling; he is not indugent, but just toward himself and others; he alone is free; he is king and lord, and is inferior in interpretate. but just toward himself and others; he alone is free; he is king and lord, and is inferior in inner worth to no other rational being, not even to Zeus himself. Hence—2. A person not easily excited; an apathetic person, or one who appears or professes to be indifferent to pleasure or pain. 'A Stoic of the woods, a man without a tear.' Campbell.

[L. stomachus, the gullet, esophagus, stomach, from Gr. stomachos, the throat, the gullet, from stoma, [L. stomachus, the machos, the throat, the guilet, from stoma, a mouth.] 1. A membranous receptacle, the principal organ of digestion, in which food is prepared for nourishing the body. The human stomach is of an irregularly conical or pear-shaped form; it is situated in the apicastric region, lying almost transconical or pear-shaped form; it is situated in the epigastric region, lying almost transversely across the upper and left portion of the abdominal cavity. Its largest extremity is directed to the left, its smaller to the right. Its superior orifice, where the esophagus terminates, is called the cardia; the interior orifice, where the intestine begins, the pylorus. The stomach is composed of three coats or membranes, connected by a firm but very extensive cellular tissue. The external or peritoneal coat is a dense firm membrane; the internal or mucous coat is soft and vascular: the central coat is is soft and vascular; the central coat is muscular. The glands of the stomach are situated in the mucous coat. The arteries of the stomach come chiefly from the coor the stomach come chieny from the con-liac artery, and are accompanied by veins which terminate in the venæ portæ, or veins conveying venous blood to the liver for the purpose of secreting bile. The nerves of the stomach are very numerous, and come from the eighth pair and the sympathetic parts. The lumphid versus are district. The lymphatic vessels are distri-

buted throughout the whole substance, and proceed immediately to the thoracic duct. The stomach owes its digestive powers chiefly to the gastric juice, an acid liquid which is secreted by innumerable follicles in the mucous coat, and the action of which upon various elements of food is somewhat similar to that of prolonged boiling in water. Digestion is also aided by the performance of certain well-defined stomachle movements, certain well-defined stomachic movements, which are well calculated to mix and thoroughly combine the food particles with its contained fluids. In mammals there are three kinds of stomachs, simple, complex, and compound. In the simple it consists of a single cavity, as in man and the Carnivora, &c. This is the most common form. The complex has two or more compartments communicating with each other, with no marked difference of structure, as in the kangaroo, squirrel, porcupine, &c. The Cetaces have from five to seven such compartments. The compound stomach is peculiar to the ruminants. It consists of four compartment, differing materially in Cetacea have from five to seven such compartments. The compound stomach is peculiar to the ruminants. It consists of four compartments, differing materially in size and in the structure of the lining mucous membrane. The first and largest cavity is the paumon or rumen, into which the food is first received; the second, the honeycomb or reticulum, so named from its lining membrane forming deep polygonal cells; the third, the psalterium or omasum, called 'manyplies' or 'moniplies' (Scottish), from its foliated structure. All these three compartments are merely useful in the precompartments are merely useful in the pre-paring the food for the fourth or true stom-ach, called also reed or abomasum, where the gastric julce is secreted and food finally digested. See RUMINANTIA.—2. Any spe-cialized cavity for the digestion of food, such as the digestive cavity in Hydrozoa, &c.—3. The desire of food caused by hunger; appetite; as, a good stomach for roast beef.

In geol. a layer of any deposited substance, as sand, clay, limestone, &c., which is spread out over a certain surface by the action of water, or in some cases by wind, especially such a layer when forming one of a number supernyer when forming one of a number super-posed. The deposition of successive layers of sand and gravel in the bed of a river, or in a canal, affords an illustration both of the form and origin of strata. Geologists gene-rally make a distinction between a stratum and a bed, restricting the latter term to the thicker kind of strata; others, however, use the terms synonymously. Strata may be said to vary in thickness from a few inches to several feet. A single stratum again is to several teet. A single statum again is often seen to be made up of thinner layers, called lannine. Strata are separated from each other by seams or parallel planes, and sometimes by joints or fissures, forming some angle with the planes. When strata do not lie horizontally but are inclined, they do not lie horizontally but are inclined, they are said to dip towards some point of the compass, and the angle they make with the horizon is called the angle of dip or inclination. The direction or strike of the strata is indicated by a horizontal line at right angles to the dip. When strata protrude above the surface, or appear uncovered, they are said to crop out. They are said to have their planes are naralthey are said to crop out. They are said to be conformable when their planes are parallel, whatever their dlp may be; and unconformable when a set of them are connected with another, so that the planes of stratification of the one series have a different direction from that of the other series. On examining the crust of the earth we find that it consists chiefly of distinct strate of examining the crust of the earth we find that it consists chiefly of distinct strata of different materials. Strawberry (stra'he-ri), n. [A. Sax. strowberre, streow-berre, strawberry, from its habit of spreading or strewing itself along the ground.] The English name of the fruit and plant of the genus Fragaria, nat. order Rosaccæ. It is remarkable for the manner in which the receptacle, commonly called the fruit, increases and becomes succulent; the proper fruit being the small achenia which it bears upon its surface. The species are perennial plants, throwing out runners; the leaves are trifoliate, each leaflet being coarsely toothed. The receptacle is round, the leaves are trifoliate, each leaflet being coarsely toothed. The receptacle is round, and assumes a variety of colours, from a scarcely perceptible pink to a dark red. All the species are natives of temperate or cold climates, and are found in Europe, America, and the mountains of Asia. The following species afford the varieties of cultivated strawberries: (1) Wood strawberry (F. vesca), found wild in woods and on hillsides throughout Europe, and abundant in Great Britain. Of this species there are several varieties cultivated in gardens, as the red, the white, the American, and Danish Alpine strawberries; the red

Strength (strength), n. [A Sax strengthu, strength, from strang, strong; comp. length and long. See Strong.] 1. That property, attribute, or quality of an animal body which it is enabled to move itself or other bodies. The strength of animals is the muscular force or energy which they are capable of exerting; as, not to have strength arough to lift the upper of to walk. In order capane of exerting; as, not to make screngin enough to lift the arm or to walk. In order to compare the effects produced by different animals, or the same animal under different circumstances, it is usual to estimate the force required to raise or transport 1 lb. through I foot of space in I minute of time, which force is called the dynamic unit. Hence, if an animal, as a horse, for example, is capable of raising 33,000 lbs. I foot high in a minute, he must exert a force 33,000 times greater than that required to raise 1 lb. through the same space in the same time. Of the different modes of estimating human strength the most practically useful is the observation of the average effect produced daily by a labourer who continues his exertions for a number of successive days, as in transporting materials in a wheel-barrow, carrying or dragging a load, working a pump, turning a winch, rowing a boat, &c. —2. The quality of bodies by which they sustain the application of force without breaking or yielding; solidity or toughness; as, the strength of a beam; the strength of a wall; the strength of a rope. The conditions which determine the strength of a wall; the strength of a wall; the strength of a wall; the strength of a wall the strength of a like with a wall the strength of a like with a wall the strength of a like with a wall the income. of a rope. The conditions which determine the strength of solid bodies, and their power the strength of solid bodies, and their power to resist forces tending to produce fracture, are found by experiment. A force acting on solid bodies may tend to separate its parts in different ways. Thus a body may be torn asunder by a stretching or tensile force or direct pull applied in the direction. of its fibres, as in the case of ropes, &c.; or it may be broken across by a transverse strain, crushed by a pressure exerted in the direction of its length, twisted, shorn across, &c.—3. Power or vigour of any kind; ability to do or bear; capacity for exertion, whether physical, intellectual, or moral; as, strength of mind, memory, or judgment; strength of evidence, argument, or persuasion; strength of feeling, affection, and the like.

Strontia (stron'shi-a), n. (SrO.) An oxide of strontium occurring in a crystalline state, as a carbonate, in the lead-mines of Strontian, in Argyleshire, whence its name. It was discovered by Dr. Hope in 1792. It has subsequently been found in England, America, and France; but strontic minerals are rather rare. The pure earth to which the name of strontia is given is prepared from the carbonate agently like prepared from the carbonate exactly like baryta. It is a grayish-white powder, in-fusible in the furnace; of a specific gravity approaching that of baryta, having an acrid approaching that of baryta, naving an acrid burning taste, but not so corrosive as baryta, though sharper than lime, and an alkaline reaction. It becomes hot when moistened, and slakes into a pulverulent hydrate (Sr(HO)₂), dissolves in 150 parts of water at 60° and in much less at the boiling-point, forming an alkaline solution called strontia vater, which deposits crystals in four-sided tables as it cools. These crystals have the composition Sr(HO), SH,O. It is readily distinguished from baryta by forming with hydrochloric acid a chloride which crystallizes in needles, and is very deliquescent, and soluble in alcohol, to which it gives the property of burning with a crimson flame. The sulphate of strontia is found native, and some of the native varieties have a pale blue tint, whence the term celestin (which see). The nitrate of strontia is used in making fireworks, as it communicates a magnificent red colour to flame.

Style(stil), n. [Fr. style, from L. stilus, stylus,

a stake, a pale, a pointed instrument, a style for writing on waxen tablets, hence mode of a stake, a paile, a pointed instrument, a style for writing on waxen tablets, hence mode of expression; from root of stimulus, Gr. stizo, to prick, E. stick, sting (which see).] 1. A pointed instrument or iron bodkin used by the ancients for writing by scratching on wax tablets. While the pointed end was used to form the letters, the other end, which was made blunt and smooth, was used for making erasures. From the instrument of writing the word came to signify a particular manner of writing. See 3 below.—2. Anything resembling a style in being pointed; as, (a) a pointed tool used in graving; a graver. (b) A pointed surgical instrument; a probe. (c) The pin or gnomon of a sun-dial, which projects the shadow on the plane of the dial. a, Style; b, Stigma. the carpels are numerous for carpels, though when the carpels are numerous mostion, the style may be lateral, basal, vertical, included, protruded, ascending, or declinate. Viewed in reference to its direction or position, the style may be lateral, basal, vertical, included, protruded, ascending, or declinate. Viewed in reference to its form, it may be filtform, or petaloid. Viewed with reference to its divisions, it may be simple or divided; when the divisions do not extend far, it is slit; when more prolonged, partite. Thus it may be bird or bipartite, trifid or tripartite, &c. After fecundation the style generally falls off, when it is said to be caducous; but when it remains, it is said to be persistent. - 3. Manner of writing with regard to language; the peculiar manner in which a person expresses his conceptions; which a person expresses his conceptions; the particular mode or form of expressing the particular mode or form of expressing ideas in language which distinguishes one writer or speaker from another; the distinctive manner of writing which belongs to each nuthor, and also to each body of authors, allied as belonging to the same school, country, or epoch.

Proper words in proper places make the true definition of a style.

Swift.

Yet let some lord but own the happy lines, How the wit brightens and the style refines? Pope.

The style which deals in long sentences or in short sentences, or indeed which has any trick in it, is ad ast style. The style was said in a meta-phorical way, the writer declaring that the style should, as it were, involve and display the subject matter, as the drapery in a consummate statue folds over and around the figure.

Sir A. Helps.

4. Mode of presentation, especially in music or any of the fine arts; characteristic or peculiar mode of developing an idea or accomplishing a result. Style in the arts depends on the character of the artist, the subjects, the art itself, the materials used, the object aimed at, &c. The style varies in different periods, and is also influenced by differences periods, and is also influenced by differences of an art, too, have each its peculiar style. Thus in poetry there are the epic, lyric, and dramatic styles, in music, the sacred, opera, and concert styles, the vocal and instrumental styles, the sonata and symphony styles, &c.; in painting there are the historical, landscape, &c., styles.—5. External manner or fashion; often, manner deemed elegant and appropriate in social demeanour; fashion: as, the entertainment was got up in excellent style.—6. Phrase of address or appellation; formal or official designation; title; as, any one having the style of majesty 'One style to a gracious benefactor, another to a proud insulting foe.' Burks.—7. In arch. a particular character as to the gen

eral artistic idea pervading a building; as, the Gothic style, the Grecian style, the Moorish style, the Norman style, &c.—8. In chron. a mode of reckoning time with regard to the Julian and Gregorian calendar. (See GREGORIAN, JULIAN.) Style is Old or New. The Old Style follows the Julian maner of computing the months and deva (See CRESONAIA, VENEZIA, 1988). New. The Old Style follows the Julian manner of computing the months and days, in which the year consists of 365 days and 6 hours. This is something more than 11 minutes too much, and in the course of time, "Great and Pone Gregory XIII." minutes too much, and in the course of time, between Cæsar and Pope Gregory XIII., this accumulated error amounted to 10 days. Gregory reformed the calendar by retrenching 10 days, and fixing the ordinary length of the civil year at 365 days; and to make up for the old hours it was ordained that every fourth year (which we call leap-year) should consist of 366 days. But the true length of the solar year is only 365 days 5 hours 48 minutes 51.6 seconds; hence, four solar years would fall short of four years of 365 days 6 hours each, or of four Julian years, three of 365 days and one of 366 days, by 44 minutes 336 seconds, and 400 solar years would fall short of 400 Julian years by 74 hours 16 minutes, or by a little more than three days. This error it was ormore than three days. This error it was or-dained should be rectified by omitting three dained should be rectified by omitting three days in three of the four years which completed centuries; or, in other words, that the centuries divisible without remainder by 400, should alone of the centuries be accounted leap-years. Thus 1600, 2000, 2400 would be leap-years, but not 1700, 1800, 1900, 2100, 2200, 2300. This mode of correcting the calendar has been adopted at different three in cluster of the calendar has been adopted at recting the calendar has been adopted at different times in almost all civilized nations with the exception of Russia and those countries where the Greek Church is predominant, which still adhere to the Old Style. In England the Gregorian or New Style was adopted by act of parliament in 1752, and as one of the years concluding a century in which the additional or intercalary day was to be omitted (the year 1700) had elapsed since the correction by Pope Gregory, it was necessary to omit 11 instead of 10 days in the current year. Accordingly 11 days in September, 1752, were retrenched, and the 3d day was reckoned the 14th. The difference between the Old and New Styles is now 12 days.—Style of a court. New Styles is now 12 days.—Style of a court, in law, the practice observed by any court in its way of proceeding.—Juridical styles, in Scots law, the particular forms of expression and arrangement necessary to be ob-served in formal deeds and instruments.— Diction, Phraseology, Style. which is denied of the subject.—8. In gram. that which is spoken of; that of which anything is affirmed; the nominative of a verb. thing is affirmed; the nominative of a vero. In philos. (a) the mind, soul, or personality of the thinker—the Eyo; the thinking agent or principle. The object is its correlative, and uniformly expresses anything or everything external to the mind; everything or anything distinct from it—the non-Eyo. The universe itself, when considered as a unique existence, is an object to the thinker, and the very spiket itself (the mind) can and the very subject itself (the mind) can become an object by being psychologically considered. These correlatives, subject and object, correspond to the first most import-ant distinction in philosophy, viz. the ori-ginal antithesis of self and not-self.

You think, and what does thinking include? Manifestly a subject and an object—a thinking being and thought itself.

J. D. Morell.

Sublimate (sub'll-mat), a. Brought into a state of vapour by heat, and again condensed, as solid substances.

Sublimation (sub-li-mā/shon), n. 1. In chem. the act or process of sublimating; a process by which solid substances are, by the aid of heat, converted into vapour, which is again condensed into the solid state by the again contact has a substant state of mapplication of cold. Sublimation bears the same relation to a solid that distillation does to a liquid. Both processes purify the substances to which they are severally apdoes to a liquid. Both processes purify the substances to which they are severally applied, by separating them from the fixed and grosser matters with which they are connected. Sublimation is usually conducted in one vessel, the product being deposited in the upper part of the vessel as solid state, and often in the crystalline form, while the impurity remains in the lower part. If iodine, for example, be heated in a Florence flask a purple vapour rises, which almost immediately condenses in small brilliant, dark-coloured crystals in the upper part of the flask, the impurity remaining in the lower. The vapour of some substances which undergo the process of sublimation condenses in the form of a fine powder called foovers; such are the flowers of sulphur, Howers of benzoin, and others of the same kind. Other sublimates require to be in a solid and compact form, as camphor, hydrochlorate of ammonia, and all the sublimates of mercury.—2 Act of heightening or improving; what is highly refined or purified. 'Religion, the perfection, refinement, and sublimation of morality.' South. Used adjectively: Sublimation theory, in geol, and mining, the theory that the matter of mineral veins was introduced as vapour and afterwards condensed.

(c) Grandeur; vastness; elevation, whether exhibited in the works of nature or of art; as, the sublimity of a scene or of a building. 2. The emotion produced by what is sublime; a feeling produced by the contemplation of great scenes and objects, or of exalted excellence. Note. The true nature of sublimity, whether of the emotion or that which causes it, is a subject of great interest and importance in mental philosophy, and it has always been a favourite subject of speculation. The invariable condition of sublimity in objects, either material or moral, is vastness, power, or intensity. The invariable condition of the emotion of sublimity—that which distinguishes this emoinvariable condition of the emotion of sub-limity—that which distinguishes this emo-tion from every other emotion—is a com-prehension of this vastness or power, with a simultaneous feeling of our own compara-tive insignificance. The antithesis to the emotion of sublimity is the emotion of cou-tempt. In every case of sublimity in ma-terial objects, whatever feelings may simul-taneously concur, vastness will be found to be an invariable condition—vastness either be an invariable condition—vastness either of form or of power, as in the violent dashing of a cataract, in the roar of the ocean, in the violence of the storm, in the majestic quiet of Mount Blanc, preserving its calm amidst all the storms that play around it. In the moral world the invariable condition of sublimity is intensity. Mars intensity is In the moral world the invariable condition of sublimity is intensity. Mere intensity is sufficient to produce the sublime. Lear, who appeals to the heavens, for they are old like him, is sublime from the very intensity of his sufferings and his passions. Lady Macbeth is sublime from the intensity of her will, which crushes every female feeling for the attainment of her object. Scavola, with his hand in the burning coals, exhibits an intensity of will which is sublime. In all the cases above mentioned we are moved by a vivid feeling of some greater power than our own, or some will more capable of suffering, more vast in its strength, pable of suffering more vast in its strength, than our feeble vacillating will.—3 † The sublimest or highest degree of anything;

6. In philos. that which underlies or is the 6. In philos. that which underlies or is the permanent subject or cause of all phenomena, whether material or spiritual; the subject which we imagine to underlie the attributes or qualities by which alone we are conscious of existences; that which exists independently and unchangeably, in contradistinction to accident, which denotes any of the changeable phenomena in substance, whether these phenomena are necessary or casual, in which latter case they are called accidents in a narrower sense. scance, whether these phenomena are necessary or casual, in which latter case they are called accidents in a narrower sense. The relation of accident to substance is called the relation of inherence, and corresponds to the logical relation of subject and predicate, because the substance is the subject to which are assigned the qualities, states, and relations as predicates; substance itself is the essence which is capable of these phenomena, and in spite of these changes remains the same. Substance is, with respect to the mind, a merely logical distinction from its, attributes. We can never imagine it, but we are compelled to assume it. We cannot conceive substance shorn of its attributes, because those attributes are the sole staple of our conceptions; but we must assume that substance is something different from its attributes. Substance is the unknown, unknowable substratum on which rests all that we experience of the external world.—7. 3. Self-sufficient; self-satisfied; content.

Thou art the most sufficient (I'll say for thee), Not to believe a thing. Beau. & Fl.

Not to believe a thing:

—Sufficient reason, according to the philosophical system of Leibnitz, a principle which admits nothing to exist without a sufficient reason may not be known to us. Of contingent truths or facts, a sufficient reason must be found which may be traced up through a series of preceding contingencies till they ultimately terminate in a necessary substance, which is a sufficient reason of the whole series of changes, and with which the whole series is connected. In this way Leibnitz demonstrated the being of God. The same principle has been employed in mathematics to prove the equality of symmetrical solids or magnitudes which cannot be made to coincide or to fill the same space. Playfair, in his notes to his edition of Euclid's Elements, has expressed this principle as a general axiom, thus: 'Things of which the magnitude is determined by conditions that are exactly the same, are conditions that are exactly the same, are equal to one another; or two magnitudes conditions that are exactly the same, are equal to one another; or two magnitudes A and B are equal, when there is no reason that A should exceed B, rather than that B should exceed A. By the sid of the principle of sufficient reason we can compare geometrical quantities, whether they be of one, of two, or of three dimensions, nor is there any danger of being misled by this principle so long as it is confined to the objects of mathematical investigation; but in physical and metaphysical questions it cannot be applied with equal safety, because in such cases we have seldom a complete definition of the thing which we reason about, or one which includes all its properties.—SYN. Enough, adequate, competent, full, satisfactory, ample, abundant.

The Greek and Arabic words are from Per. shakhara, Prakrit sakkara, Skr. çarkard, sugar. The Sanskrit form signified originally grains of sand, and was transferred to sugar which resembles such grains. The root is Skr. çri, to break into fragments.] 1. A well-known sweet granular substance, prepared chiefly from the expressed juice of the sugar-cane (Saccharum officinarum), but obtained also from a great variety of other plants, as maple, beet-root, birch, parsnip, &c. The process of manufacturing cane-sugar consists, generally, in pressing out the juice of the canes by passfacturing cane-sugar consists, generally, in pressing out the juice of the canes by passing them between the rollers of a rolling-mill. (See SUGAR-MILL.) The juice is received in a shallow trough placed beneath the rollers. This saccharine liquor is concentrated by bolling, which expels the water; lime is added to neutralize the acid that is usually present; the grosser impurities rise to the surface, and are separated in the form of soum. The liquor now requires to be concentrated or freed from water, which is generally done by boiling in vacuum-pans, and the sugar having taken a crystallized form, the molasses is removed by a centrifugal machine, leaving the sugar in the state known in commerce by the name of raws or mussowado sugar. This is further of raw or muscovado sugar. This is further

Thus clarified it takes the names of lump, leaf arising the state of the state Thus clarified it takes the names of lump, loaf, refined, &c., according to the different degrees of purification. The manufacture of sugar from beet-root is carried on to a very considerable extent in France, Germany, Austria, Belgium, Holland, Russia, &c. in the United States and in Canada great quantities of sugar are obtained from the sap of the sugar-maple (Acer accharinum). Sugar is a proximate element of the vegetable kingdom, and is found in most ripe fruits and many farinaceous roots. By fermentation sugar is converted into alcohol, and hence forms the basis of those substances, as molasses, grapes, apples, malt, &c., which are used for making intoxicating liquors. The West Indies, Brazil, British Guiana, and Java are the principal sources whence our supare the principal sources whence our sup-plies of cane-sugar are derived; the sugar used on the Continent is chiefly obtained plies of cane-sugar are derived; the sugar used on the Continent is chiefly obtained from the beet. Sugar was only vaguely known to the Greeks and Romans; it seems to have been introduced into Europe during the time of the crusades. The cane was grown about the middle of the twelfth century in Cyprus, whence, some time later, it was transplanted into Madeira, and about the beginning of the sixteenth century it was thence carried to the New World. Of all vegetable principles it is considered by many eminent physicians as the most wholesome and nutritious. Chemically, sugar is the representative of a class to which the name of sucrose or saccharose is given. Besides the sucroses the chemist is acquainted with another group of bodies represented by the sugar of most fruits, which he calls glucoses. The sucroses have the general formula $n \, C_0 \, H_{12} \, O_0$; the glucoses, the general formula $n \, C_0 \, H_{12} \, O_0$, being a whole number, whether unity or greater than unity is not as yet certainly known). When completely oxidized all sugars yield carbon dioxide and water; much heat is evolved during the oxidation.—2. That which resembles sugar in any of its properties; as, sugar of lead, the acetate of lead, called saccharum saturn by the older chemists, from a supposed resemblance in its crystals to sugar, or from the acetate of lead called saccharum saturniby the older chemists, from a supposed resemblance in its crystals to sugar, or from their having a slight sweetness in the mouth. Sugar of lead, though poisonous, is useful in medicine, having a strongly detersive quality; and it is much employed in calico-printing.—3. Sulphamate (sul'fa-mat), n. See SULPHA-

Sulphamic (sul-fam'ik), n. Having sul-phur and ammonium as the characteristic the ammonium sait of which is produced by the action of dry ammonia on dry sulphur trioxide. It may be regarded as sul-phuric acid in which one OH group is re-

phur trioxide. It may be regarded as sulphuric acid in which one OH group is replaced by NH₂; thus, SO₂ \ \ \frac{OH}{NH_2}. It is a monobasic acid, forming salts called sulphamates; of these ammonium sulphamate, SO₂ \ \ \ \frac{NH_4}{NH_2}. is one of the best known.

Sulphamide (sul'fa-mid), n. (N₂H₄SO₂) A compound which may be regarded as two molecules of ammonia in which two hydrogen atoms are replaced by the group SO₂.

Sulphate (sul'fat), n. [From sulphur.] A salt of sulphuric acid. Sulphuric acid is dibasic, forming two classes of sulphates, viz. neutral sulphates, in which the two hydrogen atoms of the acid are replaced by metal, and acid sulphates, in which one hydrogen atom only is so replaced. The general formula of the former class is M₂SO₄, and of the latter MHSO₄. (M represents a monovalent metal.) Of the sulphates, some are found native; some are very soluble, some aparingly soluble, and some insoluble. All those that are soluble are recognized in solution by the test of nitrate or shloride of All those that are soluble are recognized in solution by the test of nitrate or chloride of barium, which causes a white precipitate of sulphate of barium, insoluble in acids. All the insoluble sulphates, when fused with carbonate of soda, yield sulphate of soda, which may be recognized as above. Some neutral sulphates occur in the anhydrous state, and others occur combined with water. The most important sulphates are— sulphate of aluminium and potassium, or alum; sulphate of ammonium, employed for making carbonate of ammonia; sulphate of making carbonate of ammonia; sulphate of copper, or blue vitriol, much used as an eschanotic in surgery, and also used in dyeing and for preparing certain green pigments; sulphate of iron, or green vitriol, used in making ink, and very extensively in dyeing and calico-printing; it is also much used in medicine; sulphate of calcium, or gypsum; sulphate of magnesium, or Epsom salte; sulphate of mense, used in calico-printing; sulphate of mercury, used in the preparation of corrosive sublimate and of calomel; bisulphate of potash, much used as a flux in mineral analysis; sulphate of sodium, or Glauber's salts; sulphate of quine, much used in medicine; sulphate of sodium, or Glauper's saite; sulphate of quin-ine, much used in medicine; sulphate of zinc, or white vitriol, used in surgery, also in the preparation of drying oils for var-nishes, and in the reserve or resist pastes of the calico-printer. Many double sulphates are known

Sulphatic (sul-fat'ik), a. Relating to, containing, or resembling a sulphate.

Sulphide (sul'fid), n. A combination of sul-phur with any other element, or with a body which can take the place of an element; a sulphuret.

The susphides are, for the most part, analogous in composition to the oxides, and like the latter may be divided into acid and basic susphides, or sulphur acids and sulphur bases, which are capable of must may together and forming sulphur salts. Double susphides, a compound of two sulphides, as sulpharsenia acid, or pentasulphide of a result, and sulpharsenia acid, or pentasulphide of arsenic, and sulphide of dium.—Metallic sulphide, a compound of sulpharsenia acid.

Sulphocyanic (sul'fō-sī-an-ik), a. Sulphocyanic (sulfo-st-an-ik), a. Of, pertaining to, or containing sulphur and cyanogen, or derived from sulphocyanogen.—
Sulphocyanic acid (CN HS), an acid occurring in the seeds and holosoms of cruciferous plants, and in the saliva of man and the sheep.
It is a colourless liquid of a pure acid taste, and smells somewhat like vinegar. It colours the salts of peroxide of from blood-red. It yields salts called sulphocyanotts on It yields salts called sulphocyanates, or sometimes sulphocyanides.

Sulphocyanogen (sul'fò-si-an"o-jen), n. ((CN)₂S.) A compound of sulphur and cyanogen, called also sulphocyanic anhydride. It is obtained in the form of a deep yellow amorphous powder, insoluble in water, alcohol, and ether, but is dissolved by strong sulphpria edd

cohol, and ether, but is dissolved by strong sulphuric acid.
Sulphoindigotic (sul'fō-in-di-got"ik), a. Pertaining to, derived from, or containing sulphuric acid and indigo. Written also Sulphindigotic.—Sulphoindigotic or sulphindigotic acid (C₈ H₈ NO. SO₃), an acid formed by the action of sulphuric acid on indigo. When 1 part of pure indigo is added to 8 parts of sulphuric acid, the addition of water causes the deposition of a purple powder called sulphopurpuric acid, while a blue solution is obtained. The blue solution contains two acids, sulphoindigotic acid. Sulphopurpuric Acid (sul'fō-pēr-pū"rik asid), n. See under SULPHOINDIGOTIC. Sulpho-salt, Sulphosel (sul'fō-salt, sul'fō-salt, sul'fō-

Sulphur (sulfer), n. [L. sulfur, sulphur.]
1. Sym. S. At. wt. 32. Brimstone, an elementary non-metallic combustible substance, which has been known from the earliest ages of the world. It occurs in great abundance in the mineral, sparingly in the vegetable, and still more sparingly in the animal kingdom. It occurs sometimes pure or merely mixed, and sometimes no hemical combination with oxygen and various metals, forming sulphates and sulphides. It is found in greatest abundance

and purity in the neighbourhood of vol-cances, modern or extinct, as in Sicily; and, as an article of commerce, is chiefly im-ported from the Mediterranean. That which is manufactured in this country is obtained by the roasting of iron pyrites. It is com-monly met with in two forms; that of a compact, brittle solid, and a fine powder. It is nearly tasteless, of a greenish yellow colour, and when rubbed or melted emits a peculiar odour. It specific gravity is 1'96; it is insoluble in water, and not very readily soluble in alcohol, but is taken up by spirits of turpentine, by many oils, and by carbon of turpentine, by many oils, and by carbon disulphide. It is a non-conductor of elec-tricity. It is readily melted and volatilized. It fuses at 282° Fahr., and between 232° and It fuses at 282° Fahr., and between 282° and 280° it possesses the greatest degree of fluidity, and when cast into cylindrical moulds forms the common roll-sulphur of commerce. It possesses the peculiar property of solidifying at a higher degree, or when raised to 320°. Between 480° and 480° it is very tenacious. From 480° to its boiling-point (792°) it again becomes liquid. At 792° it rises in vapour, and in close vessels condenses in the form of a fine yellow powder, called flowers of sulphur. When sulphur is heated to at least 430°, and then poured into water, it becomes a ductile mass, and may be employed for taking the mass, and may be employed for taking the impressions of seals and medals. Sulphur impressions of seals and medals. Sulphur exists in two distinct crystalline forms, and also as an amorphous variety: these modifications are characterized by differences in specific gravity, in solubility in various liquids, and in many other points. Sulphur combines with oxygen, hydrogen, chlorine, &c., forming various important compounds. &c., forming various important compounds. It unites also with the metals, forming sulphides. It is of great importance in the arts, being employed in the manufacture of gunpowder, lucifer-matches, vulcanite, and sulphurous and sulphuric acids. It is also employed in medicine, and for various other purposes. Crude sulphur, the result of the distillation of native sulphur.—Sulphur group, the elementary substances sulphur, selenium, and tellurium; all having a strong attraction for oxygen.—Roll or stick sulphur, sulphur refined and cast into wooden moulds.—2.† Considered as that of which moulds. - 2. † Considered as that of which lightning consists.

Sulphureousness (sul-fü'ré-us-nes), n. The state or quality of being sulphureous. Sulphuret (sul'fü-ret), n. Same as Sulphide. Sulphuret (sul'fü-ret-ed), a. Applied to bodies having sulphur in combination.—Sulphuretted hydrogen (H₂S), a compound formed when hydrogen and sulphur come in contact in the nascent state. It is a transparent colourless gas, recognized by its peculiar fetid odour, resembling that of putrid eggs. It is very deleterious to animal life, and is often formed where animal life, and is often formed where animal matters or exprements outrefy. It is the life, and is often formed where animal matters or exorements putrefy. It is the active constituent of sulphureous mineral waters. It is also known by the name of Hydrosulphuric Acid. Sulphydric Acid, and Hydrothionic Acid. It is usually prepared by decomposing a metallic sulphide, especially sulphide of iron or of antimony, by means of hydrochloric or sulphuric acid. Sulphylaric (sul-fd'rik), a. Pertaining to or obtained from sulphur.—Sulphuric acid, oil

of vitriol, a most important acid, discovered by Basil Valentine towards the close of the fifteenth century. It was formerly procured by the distillation of dried sulphate of iron, by the distillation of dried sulphate of iron, called green vitriol, whence the corrosive liquid which came over in the distillation, having an oily consistence, was called oil of vitriol. It is now prepared in this and most other countries by burning sulphur, or more frequently iron pyrites, in closed furnaces, and leading the fumes, mixed with oxides of nitrogen, into large leaden chambers, into which jets of steam are continuously sent. The oxides of nitrogen are produced by the sction of sulphuric acid upon nitre sent. The oxides of nitrogen are produced by the action of sulphuric acid upon nitre contained in pots, which are placed between the sulphur ovens and the chambers. The sulphur dioxide takes away part of the oxygen from the oxides of nitrogen, which are again oxidized by the air in the chambers. The sulphur trioxide produced unites with the steam to form sulphuric acid. The acid. The suppur trickide produced unites with the steam to form sulphuric acid. The acid produced in the chamber is condensed in leaden vessels until it reaches a certain gravity, when it is run into glass, or sometimes into platinum vessels, where the condensation is continued. Pure sulphuric acid is a dense, cily, colourless fluid, having, when strongly concentrated, a specific gravity of about 1.8. It is exceedingly acid and corrosive decomposing all animal and and corrosive, decomposing all animal and vegetable substances by the aid of heat. It vanites with alkaline substances, and separates most of the other acids from their combinations with the alkalies. It has a very great affinity for water, and unites with very great among the water, and unless when it in every proportion, producing great heat; it attracts moisture strongly from the atmo-sphere, becoming rapidly weaker if exposed. The aulphuric acid of commerce is never pure, but it may be purified by distillation. With bases sulphuric acid forms salts called sulphates, some of which are neutral and sulphates, some of which are neutral and others acid. By concentrating sulphuric acid as far as is possible without decomposition, and cooling the liquid so obtained, crystals of the true acid, H₂SO₂, are formed. The ordinary acid is a hydrate of H₂SO₂ of varying composition. A form of sulphuric acid known as Nordhausen acid is prepared by heating green vitriol in closed vessels, it is a solution of sulphur trioxide in sulphuric acid (H₂SO₂SO₂), or it may be regarded as pyrosulphuric acid (H₂SO₂). The best test of the presence of sulphuric acid, whether free or combined, is a soluble compound of barium. Thus, when a solution of clioride barium. Thus, when a solution of chloride of barium is added to a liquid containing sulphuric acid it causes a white precipitate, viz. sulphate of barium, which is not only insoluble in water, but in the strongest acids. Of all the acids the sulphuric is the most extensively used in the arts and is the most extensively used in the arts, and is in fact the primary agent for obtaining almost all the others by disengaging them from their saline combinations. Its uses to the all the others by disengaging them from their saline combinations. Its uses to the scientific chemist are innumerable. In medicine it is used in a diluted state as a refrigerant. See SULPHATE.—Sulphuric ether, ethylic, vinic, or ordinary ether— $(C_2H_{5,2}O-a$ colourless transparent liquid, of a pleasant smell and a pungent taste, extremely exhilarating, and producing a degree of intoxication when its vapour is inhaled by the nostrile. It is produced by distilling a mixture of equal weights of sulphuric acid and alcohol, and by various other means. Its specific gravity is 0.720. It is extremely volatile and highly inflammable; and its vapour, mixed with oxygen or atmospheric air, forms a very dangerous explospheric air, forms a very dangerous explosive mixture. It dissolves in 10 parts of water, and is miscible with alcohol and the fatty and volatile oils in all proportions. It is employed in medicine as a stimulant and is employed in medicine as a stimulant and antispasmodic. The vapour of ether has been administered with success to patients when about to undergo surgical operations, but it is now to a great extent superseded by chloroform. True sulphuric ether, known also as sulphate of ethyl— $(C_2H_g)_2SO_d$ —Is an oily liquid, of burning taste and etheresi odour, resembling that of peppermint, of sp. gr. 1·120, and almost incapable of being distilled without decomposition, as at a temperature of about 280° it resolves itself into alcohol, sulphurous acid, and olefant temperature of about 230° it resolves itself into alcohol, sulphurous acid, and olefiant gas.—Sulphurc oxide, or sulphur trioxide (80₃), is a white crystalline body produced by the oxidation of sulphurous oxide (which see). When this oxide is thrown into water it combines rapidly with the latter to form sulphuric acid.

Sulphurine (sulfer-in), a. Pertaining to

Sulphurous (sul'fer-us), a. Made or impregnated with sulphur; like sulphur; containing sulphur. 'There's the sulphurous pit.' Shak.—Sulphurous oxide, a gas formed by the combustion of sulphur in air or dry oxygen. It is transparent and colourless, of silectrophilates are presented and colourless. of a disagreeable taste, a pungent and suffocating odour, is fatal to life, and very injurious to vegetation. At 45°, under the pressure of two atmospheres, it becomes liquid, sure of two atmospheres, it becomes liquid, and also at 0" under the pressure of one atmosphere. It extinguishes fiame, but is not itself inflammable. It has considerable bleaching properties, so that the fumes of burning sulphur are often used to whiten straw, and silk and cotton goods. This gas is also called Sulphur Dioxide; when led into water it forms sulphurous acid (H₂ SO₂). This acid readily takes up oxygen, passing into sulphuric acid; it is dibasic, forming salts called sulphites.

Summer (sum'er), n. One who sums; one who casts up an account.
Summer (sum'er), n. [A. Sax. sumor, sumer; common to the Teutonic languages; O. H.G. and Icel. sumar, G. and Dan. sommer, Sw. sommar, D. somer, zomer. The origin is doubtful, though probably the root is that of sun.] 1. That season of the year when the sun shines most directly upon any region; the warmest season of the year. North

of the equator it may be roughly said to include the months of June, July, and August. Astronomically considered, summer begins in the northern hemisphere when the sun enters Cancer, about the 21st of June, and continues for three months, till September 23d, during which time the sun, being north of the equator, shines more directly upon this part of the earth, which renders this the hottest period of the year. In latitudes south of the equator just the opposite takes place, or it is summer there when it is winter here. The entire year is also sometimes divided The entire year is also sometimes divided into summer and winter, the former signifying the warmer and the latter the colder part of the year.—2. Sax. sol; these forms coinciding with L. sol; also (with common interchange of s and h) Gr. helios, W. haul, Corn. houl, Armor. heal. From a root meaning to shine.) 1. The splendid orb or luminary which, being in or near the centre of our system of worlds, gives light and heat to all the planets, and is therefore the primary cause of all the motions and changes effected on the surface of our globe by those mighty the surface of our globe by those mighty agents. All the planets and comets of our system revolve round the sun as a common centre, at different distances and in different periods of time. Its mean apparent diameter is about 32 minutes, and its mean distance ls about 52 minutes, and its mean distance from the earth about 92,000,000 of miles. Its real diameter is 860,000 miles, and hence its volume is equivalent to about 1½ million times the volume of our earth; but its mean density is only a fourth of that of the earth. It revolves on its axis from west to east in 25½ of our mean solar days, the axis being inclined at an angle of 82° 40′ to the plane of the ecliptic. When viewed through inclined at an angle of 82° 40′ to the plane of the ecliptic. When viewed through powerful telescopes the sun's disc is observed to have large and perfectly black spots upon it, several of which are usually visible at once. These spots present the appearance of black irregular patches, and have been proved to be hollows in the luminous surface of the sun. (See Solar spots under Sollar.) These spots appear and disappear very irregularly, some lasting for weeks and months, others only a day. Around the spots, and on other places, there are often masses brighter than the general surface, called faculte or torches. The general surface tiself is not uniform, but appears mothed, and made up of bright roundish patches, with soft edges, sprinkled irregularly on a tied, and made up or origin roundish patches, with soft edges, sprinkled firregularly on a less luminous background. The luminous surface of the sun is called the photosphere. The photosphere is overlaid by an atmosphere which is invisible under ordinary circumstances, but reveals itself to the spectroscope, and at a total eclipse forms the white halo or corona which is seen surrounding the moon. Within the corona are seen oddly shaped masses of a red colour, projecting con-siderablant review resists hard the snaped masses of a red colour, projecting considerably at various points beyond the moon's edge, and these projections are united by a continuous belt of similar, though less vivid colour. This belt is called the chromosphere, and these reddish masses are great clouds or flames of incandescent hydrogen. The spectroscope has shown the sun to be composed of substances identical, partly at least, with those composing the earth, as hydrogen, sodium, iron, magnesium. The matter is so intensely hot as to be largely in the state of vapour. The amount of light sent forth by the sun is not exactly measurable, but the amount of heat has been pretty accurately computed, and it is certainly enormous. It is equivalent in mechanical effect to the action of 7000 horse-power on every square foot of the solar surface, or to every square foot of the solar surface, or to the combustion on every square foot of up-wards of 13½ cwts. of coal per hour.—2. In popular usage, the sunshine; a sunny place; a place where the beams of the sun fall; as, to stand in the sun, that is, to stand where the direct rays of the sun fall.—8. motion of the beam into a rotatory motion. In the annexed figure the sun wheel a, is a toothed wheel fixed fast to the axis of the fly-wheel, and the planet wheel b is a similar wheel botted to the lower end of the connecting-rod c; it is retained in its orbit by a link at the back of both wheels. By the reciprocating motion of the connecting-rod the wheel b is compelled to circulate round the wheel a, and in so doing carries the latter along with it, communicating to the fly-wheel a velocity double of its own.

given to dials are almost infinite. given to dials are almost infinite. The most common form is the horizontal dial, having the piane of the dial parallel to the horizon, and consequently making with the style an angle equal to the latitude of the place, since the style must always point to the north pole. The hour lines intersect each other at the point where the style intersects the dial plane, and the angles they make other at the point where the style intersects
the dial plane, and the angles they make
with one another and with the meridian
line, or line for twelve o'clock, depend on
the latitude. In vertical dials the position
of these lines depends on the latitude and
the aspect of the face.

'Surd modes of articulation.' Kenriok.—3. In math. not capable of being expressed in rational numbers; as, a surd expression, quantity, ornumber. See the noun. 4. In phonetics, uttered with breath and not with voice; devoid of proper vocality; not sonant; toneless; specifically, a term applied to the hard mute consonants of the alphabet. See the noun.

Surd (serd), n. 1. In math. an irrational quantity; a quantity which is incommensurable to unity. Or, a surd denotes the root of any quantity, when that quantity is not a complete power of the dimension required by the index of the root. Hence, the roots of such quantities cannot be expressed by rational numbers. Thus the square root of 2(or √2), the cube root of 4(√3/4), the fourth root of 7(√7), &c., are surds, for they cannot be expressed by regional numbers.

2(or $\sqrt{2}$), the cube root of $4(\sqrt{4})$, the fourth root of $7(\sqrt[4]{7})$, &c., are surds, for they cannot be expressed by rational numbers.—2. In phonetics, a consonantal sound uttered with breath and not with voice; a nonsonant consonant; a hard check; as, p, f, s, t, k, as opposed to b, v, z, d, g, which are called soft checks, flats, or sonants.

The exterior part of anything that has length and breadth; one of the limits that terminates a solid; the superficies; outside; as, the surface of a the sen'face of a diamond; the surface of the body; the surface of a cylinder; an even or an uneven surface. Popularly, surface is often used to signify, not merely the outside or exterior boundary of any substance, but also a certain thickness of the exterior material part. In this way we speak of the surface of the earth, the surface of the soil, of taking off the surface of anything, &c.—2. In geom. a superficies; that which has length and breadth only, and so distinguished from a soil, which has length, breadth, and thickness. The externities of a surface are lines, and the length only, and from a solid, which has length, breadth, and thickness. The ex-tremities of a surface are lines, and the intersections of one surface with another are intersections of one surface with another are also times.—A plane surface is that in which any two points being taken the straight line between them lies wholly in that surface.—A surface which may be cut by a plane through any given point, so that the line of common section of the plane and surface may be a curve, is called a curved surface; as the surface of a sphere, cylinder, or cone. Surfaces are distinguished algebraically by the nature and order of their equations. Thus, we have surfaces of the first order, or plane surfaces, and surfaces of the second order, or curved surfaces. Surfaces are also distinguished by their mode of generation; thus the surface of a sphere is generated by the revolution of a semicircular are about the diameter, which remains fixed. In the revolution of a semicircular arc about the diameter, which remains fixed. In physics, a surface is supposed to be composed of a number of material particles, placed together side by side, without any opening or interstice between them. Such a surface, therefore, cannot be said to be absolutely destitute of thickness, but may be regarded as a film of matter whose thickness is the distributed. ness is indefinitely small.—Tabular surface, a surface generated by a circle of a given radius, which moves with its centre on a given curve, and its plane at right angles to the tangent of that curve.—Rude surface, a surface described by the motion of a straight surface described by the motion of a straight line, which neither remains parallel to a given line nor always passes through a given point, as conoidal surfaces. — Developable surface, a surface that can be unwrapped in a plane without any doubling of parts over one another, or separation, as the surfaces of the cylinder and cone. — Undevelopable surface, a surface that cannot be developed in the plane. — 3. Outward or external appearance; what appears on a slight or casual view or without examination; as, this arrangement, on the surface, was very advantageous. — 4. Surmulot (ser'mi-lot), n. [Fr., from saw, O.Fr. sor, reddish-brown, sorrel, and mulot, a field-mouse.] A name given by Buffon to the brown rat (Mus decumanus).

Surname (sér'nâm), n. [Frefix sur, over and above, and name.] 1. An additional name; a name or appellation added to the baptismal or Christian name, and which becomes a family name. Surnames with us originally designated occupation, estate, place of residence, or some particular thing or event that related to the person. Thus william Rufus or red; Edmund Ironsides; Robert Smith, or the smith; William Turner. Surnames seem to have been formed at first by adding the name of the father to that of the son, and in this manner several of our surnames were produced. Thus from Thomas William's son we have Thomas William's rom John's son we have Johnson, &c.

There still, however, wanted something to ascertain gentility of blood, where it was not marked by the actual tenure of land. This was supplied by two innovations, devised in the eleventh and twelfth centuries, the adoption of surnames and of armorial bearings.

G. schwalbe, awallow.] A common name of a number of insessorial birds of the fissirostral section of swallow.] A common name of a number of insessorial birds of the fissinostral section of the order, several species of which are well-known in this country. They are remarkable for their dense plumage, extreme length of wing, and velocity of flight, while their feet and legs are comparatively weak. Their food consists of insects, which they catch in the air, and thus they pass more of their time upon the wing than most other birds. Their bill is short and very broad at the base, so that the gape is remarkably wide. They are found almost all over the world. In temperate climates the swallows are migratory birds, marking the arrival of spring by their coming, and giving notice that summer is over by their departure to warmer regions. The common species in Britain are the chimney swallow (Hirundo rustice), the house-martin (H. urbica), and the sand-martin (H. riparia). The chy jey swallow has the tail very deeply forked, the two outside feathers being far longer than any of the others. It is about 59 inches in length. bar across the breast are bluish black, the forehead and throat chestnut, the under surface white. The nest is cup-shaped,

made of mud, and placed in chimneys, under open roofs, or in similar situations. The house-martin is glossy black above, whitish below and on the rump, and the tail is not so markedly forked. It builds a hemispherical nest of mud or clay under eaves, &c., with the entrance on one side. The sand-martin is smaller than either of the above, brownish on the upper parts, white below, with the tail moderately forked. It makes its nest in steep sandy banks, excavating by means of its bill a gal-

torked. It makes its nest in steep sandy banks, excavating by means of its bill a gallery 18 inches or more in depth for the purpose. The purple martin (H. purpurea) is a very common species in North America, and is a great favourite in the northern parts, where, like the British species, it serves as a herald of spring. Several other species belong to America.

the founder of the New Jerusalem Church,
alluding to the New Jerusalem spoken of
in the book of the Revelation, and conceived
that the members of this church were gifted
with peculiar insight into spiritual things. that the members of this church were gifted with peculiar insight into spiritual things. The Swedenborgians believe that the regenerate man is in direct communication with angels and with heaven. They maintain that the sacred Scriptures contain three distinct senses, called celestial, spiritual, and natural, which are united by correspondences, and are accommodated respectively to particular classes, both of men and angels. They hold that there have been various general judgments ending particular dispensations of divine revelation. The last was in 1757, when Swedenborg received the office of teaching the doctrines of the new church promised in the Apocalypse. As this church is to be eternal there will be no other general judgment, but each individual is judged soon after death. There are numerous societies of them both in Great Britain and America.

family Cypselids. They have an outward re-semblance to the swallows, but differ much from them in various structural points. The common swift (C. agus) has the greatest powers of flight of any bird that visits Britain. Its colour is in general a sombre or sooty black, with a grayish-white patch under the

chin. The beak is black, shorter than that of the swallow, and without the lateral bristles. The wings are even longer than those of the swallow, and are stokle-shaped. The tarsi are short, and feathered to the toes, which are all directed forwards. The toes, which are all directed forwards. The swifts pass most of their time in the air, where they pursue their insect prey. Their flight is swift and shooting, and their scream very different from the twittering of the swallow. They build their nests in holes in the walls of houses, in rocks, and some-times in hollow trees. The swift reaches its times in hollow trees. The switt reaches its summer quarters later, and leaves earlier than the swallows. Another species, the white-bellied or Alpine swift (C. alpinus), is known in this country, but it is only a rare straggler. The weight of the swift is most disproportionately small to its extent of wing, the former being scarcely an ounce, the latter 18 inches, the length of the body being near 8 inches. Syllogism (sil'lō-jizm), n. [Fr. syllogisme, L. syllogismus, from Gr. syllogismos, a syllogism, from syllogizomai, to reckon all together—syl for syn, with, together, and logizomai, to reckon, to conclude by reasoning, from logos, word, reason, &c., from lego, to gather, to collect, to reckon all together.] 1. In logic, a form of reasoning or argument, consisting of three propositions, of which the two first are called the premises, and the last the conclusion necessarily follows from the premises; so that if the two first propositions are true the conclusion must be true, and the argument amounts to two first propositions are true the conclusion must be true, and the argument amounts to demonstration. Thus, a plant has not the power of locomotion; an oak is a plant; therefore an oak has not the power of locomotion. These propositions are denominated the major, the minor, and the conclusion. The three propositions of a syllogism are made up of three ideas or terms, and these terms are called the major, the minor, and the middle. The subject of the conclusion is called the minor term; its predicate is the major term, and the middle term is that which shows the connection between the major and minor term in the between the major and minor term in the conclusion; or it is that with which the major and minor terms are respectively compared. Syllogisms are divided by some into single, complex, conjunctive, &c., and by others into categorical, hypothetical, conditional, &c. What is called the figure of a syllogism is the proper disposition of the middle term with reference to the major and minor terms. The figures are by many logicians reckoned four, but the fourth is now usually considered as both unnatural and unnecessing being only an awkward inversion of the first, to forms of which indeed, all the other figures are held to be reducible. The mood of a syllogism is the designation of its three propositions, according to their quantity

and quality. The quantity and quality of propositions, in logic, are marked by arbitrary symbols, as Å, E, I, O. Every assertion may be reduced to one of four forms—the universal affirmative, marked by E; the particular affirmative, marked by E; the particular negative, marked by I; and the particular negative, marked by O. From these, by combination, all syllogisms are derived. In order to remember the figures, certain memonic words have been long these, by combination, all syllogians are derived. In order to remember the figures, certain mnemonic words have been long used by writers on logic; thus, under the first figure, we have Barbara, Celarent, Daril, Feric; under the second, Cesare, Cameatres, Festino, Baroko; under the third, Darapti, Disamis, Datisl, Felapton, Bocardo, Feriso; and under the fourth, Bramantip, Camenes, Dimaris, Fesapo, Fresison. (See these words.) Each of these words designates a particular mood. The rules of syllogism may be thus briefly expressed: (a) one at least of the premises must be affirmative, and one at least universal; (b) the middle term must enter universally in one of the premises; and (c) the conclusion must not speak of any term in a wider sense than it was spoken of in the premise in which it entered. A term universally spoken of is either the subject of a universal affirmative, or the predicate of any negative. Syllogisms are nothing else than reasoning reduced to form and method, and it is well to know, when an argument is presented in a nursiling on vernleying form. gisms are nothing else than reasoning reduced to form and method, and it is well to know, when an argument is presented in a puzzling or perplexing form, with perhaps a suppression of one of its essential propositions, how to supply the suppressed premises and put the argument into regular order; the truth or fallacy of the reasoning then become apparent at a glance.—2. Synagogues were erected not only in towns and cities but also in the country, especially near rivers, that they might have water for their purifications and ceremonies. At the extreme east end of the building was the holy ark, containing and ceremonies. At the extreme east end of the building was the holy ark, containing copies of the Pentateuch; in front of this was a raised platform for the reader or preacher. The men sat on one side of the synagogue, the women on the other, a partition 5 or 6 feet high dividing them. The chief seats for which the soribes and Pharisess strong were situated near the aust and chief seats for which the scribes and Pharises strove were situated near the east end. The synagogue was governed by a council or college of elders, over whom was a president called the ruler of the synagogue. The service consisted of prayers, reading the Scriptures, and preaching and expounding of them. The chief ruler or one of the council might call upon any one present to address the recollege or even a strateger might. council might call upon any one present to address the people, or even a stranger might volunteer to speak. Properly defined, synonyms are words of the same language and the same grammatical class, identical in neaning; or, more generally, synonyms are words of the same language which are the precise equivalents of each other. And if a definition of the word in the singular be insisted on, we may say that a noun or other part of speech, identical in meaning with another word of the same language and the same grammatical class, is the synonym of that word; or, less specifically, a synonym is a word identical in meaning with another word of the same language and the same grammatical class. But though this is the proper definition of true synonyms, it is by no means the ordinary use of the term, which is gener-

\mathbf{T} .

T is the twentieth letter of the English T is the twentieth letter of the English alphabet, a sharp mute consonant, closely allied to d, both being dentals. In forming it the tip of the tongue is pressed close to the root of the upper teeth, as may be perceived in uttering the syllables at, ta, ot, to. This is also the position of the tongue for the letter d, as in the syllables ad, da, od, do; but d is uttered with voice, whereas t is entirely non-vocal. In reality, t can be hardly said to have any sound at all, its use, like that of the other sharp mutes k and p, being merely to modify the manner of uttering the vocal sound which precedes or folbeing merely to mounty the manner of utter-ing the vocal sound which precedes or fol-lows it. When t is followed by h in the same syllable, as in think, that, with, the combination forms two distinct sounds— surd or breathed, as in think, and sonant or vocal, as in that. These sounds were represame syllable, as in think, that, with, the combination forms two distinct sounds—surd or breathed, as in think, and sonant or vocal, as in that. These sounds were represented by two characters in Anglo-Saxon and Old English, and it is a pity the old letters were given up. The letters ti before a vowel, and unaccented, usually pass into the sound of sk, as in nation, motion, partial, which are pronounced nashon, moshon, parshal. In this case t loses entirely its proper sound or use, and being blended with the subsequent letter a new sound results from the combination, which is in fact a simple sound. If s or x precede ti (as in mixtion, question), t retains its own sound, though in this case many speakers soften it to ch as in church, as they also do in such words as mixture, posture. In comparing words common to the Indo-European tongues we find that (as formulated by Grimm's law) t in English (as also in Dutch, Icelandic, Gothic, &c.) corresponds to d in Latin, Greek, and Sanskrit, and to s or z in German. Thus E. tooth = L. dens, dentis, Gr. (o)dous, (o)dontos, Skr. dant, G. zahn; E. foot = L. pes (peds), pedis, Gr. pous, podos, Skr. pada, G. fuss; E. two = L. duo, Gr. dyō, Skr. dva, G. zwei; E. two = L. duo, Gr. dyō, Skr. dva, G. zwei; E. two = L. duo, Gr. dyō, Skr. dva, G. zwei; E. two = L. duo, Gr. dyō, Skr. dva, G. zwei; E. two = L. duo, Gr. dyō, Skr. dva, G. d. essen, and so on. An s before t, however, hinders this change from taking place, and hence the tin E. stand appears also in L. sto, Gr. histeni, and G. stehen. The English th, on the other hand, answers to tin Latin, Greek, and Sanskrit, and to d in German; thus E. thou = L. and Gr. tu, Skr. tram, G. du; E. three = L. tres, Gr. treis, Skr. tri, G. drei. Hence it comes that G. tag = E. day; gut= good, wasser=water, and zahm = tame. In some Latin words d has been changed to l. hence ti E. tear (n.) = l in L. lacrima (for darrima), Fr. larme, a tear. A final t has been changed to l. some Latin words d has been changed to l. hence t in E. tear (n)=l in L. tear time (for dacrima), Fr. larme, a tear. A final t has become attached to many English words to which it does not properly belong, this being particularly the case after n and s, as in tyrant, pheasant, ancient, amidst, whilst, against, dc. It has sometimes dropped out, as in best, last; so th has disappeared from worship. This letter is often doubled in the middle of words, seldom at the end, as in butt, mitt. T is often used to denote things of this form, as the T-nalace in Mantus. See out, mat. Is often used to denote things of this form, as the T-palace in Mantua. See T-BANDAGE, T-BEARD, T-CLOTH, T-IRON, T-JOINT, T-SQUARE.—To a T, exactly, with the utmost exactness; as, to suit or fit to a T. The allusion is to a mechanic's T-square, by which accuracy in making angles, &c., is secured. [Familiar.]

We could manage this matter to a T.

Tally (tal'li), n. [Fr. taille, a tally, a cut, a cutting, from tailler, to cut. See RETAIL.]

1. A piece of wood on which notches or scores are cut, as the marks of number. In purchasing and selling it was customary for traders to have two sticks, or one stick cleft into two parts, and to mark with scores or notches on each the number or quantity of goods delivered, or what was due between goods delivered, or what was due between debtor and creditor, the seller or creditor keeping one stick, and the purchaser or debtor the other. Before the use of writing, or before writing became general, this or something like it was the usual method of keeping accounts. In the exchequer tallies were formerly used, which answered the purpose of receipts as well as simple records purpose of receipts as well as simple records of matters of account. Hence the origin of exchequer bills. In former times of financial difficulty, from the period of the Norman conquest the practice had been to issue exchequer tallies. An exchequer tally was an account of a sum of money lent to the government, or of a sum for which the government would be responsible. The tally itself awaited of a second was a factorial to the control of the sum o government would be responsible. The taily itself consisted of a squared rod of hazel or other wood, having on one side notches, indicating the sum for which the tally was an acknowledgment. On two other sides opposite to each other, the amount of the sum the large of the years and the late of sum, the name of the payer, and the date of the transaction, were written by an officer called the writer of the tallies. This being called the writer of the tallies. This being done the rod was then cleft longitudinally in such a manner that each piece retained one of the written sides, and one half of every notch cut in the tally. One of these parts, the counterstock, was kept in the exchequer, and the other, the stock, only issued. When the part issued was returned to the exchequer (usually in payment of taxes) the two parts were compared, as a check against fraudulent imitation. This ancient system was abolished by 25 Geo. III. Ixxxii; and by 4 and 5 Will. IV. xv. all the old tallies were ordered to be destroyed. The size of the notches made on the tallies varied with the amount. The notch for £100 was the breadth of a barleycorn. A penny for £1 the breadth of a barleycorn. A penny was indicated by a slight slit.—2. Anything made to suit or correspond to another.

Tangence (tan'jens), n. A touching; tangency.—The point of tangence is the point of contact of a tangent line.

Tangency (tan'jensi), n. State of being tangent; a contact or touching.—Problem of tangencies, among the old geometers, a branch of the geometrical analysis, the general object of which was to describe a circle passing through given points, and touching straight lines or circles given in position, the number of data being always limited to

Tangent (tan'jent), n. [L. tangens, tangentis, ppr. from L. tango, to touch. Akin tact.]
In geom. a straight line

In geom. a straight line which touches or meets a circle or curve in one point, and which being produced does not cut it, as A, B, C, D, E, F in fig. 1. Euclid has shown that the straight line drawn at right angles to the diam-

eter of a circle, from the extremity of it, is a tangent to the circle. In trigon, the tangent of an arc or angle is a straight line touching the an arc or angle is a straight line touching the circle of which the arc is a part, at one extremity of the arc, and meeting the diameter passing through the other extremity. Thus, in fig. 2, let A H be a straight line drawn touching the circle ADE at A, one extremity of the arc AB, and meeting the diameter IB produced, which passes through the other extremity B in the point H; then AH

gent of an arc or angle is also the tangent of

of the supplement AI, or of the angels on its supplement. Thus, AH is the tangent of the supplement AI, or of the angel ACI; for it is easy to see that the definition above given applies equally to the arc AB and to the arc AI. The arc and its tangent have the arc AI. The arc and its tangent nave always a certain relation to each other; and when the one is given in parts of the radius, the other can always be computed by means of an infinite series. For trigonometrical purposes tangents for every arc from 0 degrees to 90 degrees, as well as sines, cosines, &c., have been calculated with reference to reading of a certain length and these or acc., have been calculated with reference to a radius of a certain length, and these or their logarithms formed into tables. In the higher geometry the word tangent is not limited to straight lines, but is also ap-plied to curves in contact with other curves, and also to surfaces.—Method of tangents,

the name given to the calculus in its early period. When the equation of a curve is given, and it is required to determine the given, and it is required to determine the tangent at any point, this is called the direct method of tangents; and when the subtangent to a curve, at any point, is given, and it is required to determine the equation of the curve, this is termed the inverse method of tangents. The above terms are synonymous with the differential and integral callus. — Natural tangents to revent care mous with the differential and integral cal-culus. Natural tangents, tangents ex-pressed by natural numbers.—Artificial tan-gents, tangents expressed by logarithms.— To go or fly off at a tangent, to break off suddenly from one line of action, train of thought, or the like, and go on to something

Tanghin (tan'gin), n. [The native name in Madagascar.] A deadly polson obtained from the seeds of Tanghinia venenifera. See TANGHINIA.—Trial by tanghin, a kind of ordeal formerly practised in Madagascar to determine the critics. termine the guilt or innocence of an accused person, by taking the tanghin poison. The seed was pounded and a small piece swallowed by each person to be tried. If the accused retained the poison in the system death quickly resulted—a proof of guilt; if the stomach rejected the dose little harm supervened—and innocence was established. By the influence of Christianity its use has been discontinued. Spelled also Tanguin.

Tanghinia (tan-gin'i-a), n. [See above.] A

genus of plants belonging to the nat. order Apocynacese. T. venenifera is a tree which produces the celebrated tanghin poison of Madagascar. The poisonous quality resides in the kernel, and one seed is said to be sufficient to kill twenty persons. It has smooth alternate thickish leaves, and large terminal cymes of pink flowers, which are succeeded by large purplish fruits containing a hard stone surrounded by a thick fibrous flesh. The genus is now often united with Cerbera. Tangibility (tan-ji-bil'i-ti), n. The quality of being tangible or perceptible to the touch or sense of feeling.

Tauxibility and impenerability were elsewhere Madagascar. The poisonous quality resides

Tanistry (tan'ist-ri), n. [See TANIST.] A mode of tenure that prevailed among various Celtic tribes, according to which the tanist or holder of honours or lands held them only for life, and his successor was fixed by election. According to this custom the right of succession was not in the individual, but in the family to which he belonged; that is, succession was hereditary in the family, but elective in the individual. The primitive intention seems to have been that the inheritance should descend to the oldest or most worthy of the blood and name of the deceased. This was in reality giving it to the strongest, and the practice often occasioned bloody wars in families.

They were subject to the law of tanistry, of which the principle is defined to be, that the demesne lands and dignity of chieftainship descended to the eldest and most worthy of the same blood.

Tanning (tan'ing), n. 1. The practice, operation, and art of converting the raw hides and skins of animals into leather by effecting a chemical combination between the gelatine of which they principally consist and the astringent vegetable principle called tannic acid or tannin. The object of the tanning process is to produce such a chemical change in skins as may render them unalterable by those agents which tend to decompose them in their natural state, and in connection with the subsequent operations of currying or dressing to bring them into a state of pliability and impermeability to water which may adapt them for the many useful purposes to which leather is

applied. The larger and heavier skins subapplied. The larger and heavier skins subjected to the tanning process, as those of
buffalces, bulls, oxen, and cows, are technically called hides; while those of smaller
animals, as calves, sheep, and goats, are
called skins. After being cleared of the
hair, wool, and fleshy parts, by the aid of
lime, scraping, and other means, the skins
are usually steened in an infraign of ground are usually steeped in an infusion of ground oak bark, which supplies the astringent or oak bark, which supplies the astringent or tanning principle, and thus converts them into leather. Different tanners, however, vary much in the mode of conducting the process of tanning, and also the skins in-tended for different kinds of leather require to be treated differently. Various improve-ments have been made in the process of tanning by which time and labour prepared Hierits have been made in the process of tanning, by which time and labour are much reduced; but it is found that the slow pro-cess followed by the old tanners produces leather far superior to that produced by quick processes.—2. [From their resemblance in shape to a tape.] The name common to certain internal parasites (Entozoa) constituting the order Cestoi-dea or Tæniada of the sub-kingdom Andea or Tæniada of the sub-kingdom An-nuloida, found in the mature state in the alimentary canal of warm-blooded verte-brates. Tape-worms are composed of a number of flattened joints or segments, the anterior of which, or head (which is the true animal), is furnished with a circlet of hooks and suckers, which enable it to maintain its hold on the mucous membrane of the intesnoid on the nucous membrane of the intes-tines of its host. The other segments, called proplettides, are simply generative organs budded off by the head, the oldest being furthest removed from it, and each con-taining when mature male and female organs. The tape-worm has neither mouth nor digestive organs, nutrition being effected by absorption through the skin. The length of the animal varies from a few inches to several yards. The ova do not undergo development in the animal in which the adult velopment in the animal in which the adult exists. They require to be swallowed by some other warm-blooded vertebrate, the ripe proglottides being expelled from the bowel of the host with all their contained ova fertilized. The segments or proglottides decompose and liberate the ova, which are covered with a capsule. After being swallowed the capsule bursts and an embryo, called a proscolex, is liberated. This embryo, by means of spines, perforates the tissues of some contiguous organ, or of a blood-vessel, in the latter case being carried by the blood to some solid part of the body, as the liver or brain, where it surrounds itself with a cyst, and develops a vesicle containing a fluid. It is now called a scolex or hydatid, and formerly was known as the cystic worm. The scolex is incapable of farther development till swallowed and received a second time into the alimentary ceived a second time into the alimentary canal of a warm-blooded vertebrate. Here it becomes the head of the true tape-worm, from which proglottides are developed pos-teriorly by gemmation, and we have the adult animal with which the cycle begins. Eight true tape-worms occur in man, *Tænia* Eight true tape-worms occur in man, Tænia solium, the cystic form of which produces the measles of the pig, being the most common. It exists in grape juice, in tamarinds, and several other fruits; but principally in bitartrate of potassium, or cream of tartar, from which it is usually obtained. It crystallizes in large rhombic prisms, transparent and colourless, and very soluble in water. It is inodorous and very sour to the taste. A high temperature decomposes it, giving rise to several new products. The solution of tartaric acid acts with facility upon those metals which ature decomposes it, giving rise to several new products. The solution of tartaric acid acts with facility upon those metals which decompose water, as iron and zinc. Tartaric acid is dibasic; its salts are called tartrates. Tartaric acid has a most remarkable disposition to form double salts, as the tartrate of potassium and sodium or Rochelle salts; the tartrate of potassium and antimony, or tartar emetic. There are five modifications of tartaric acid, characterized chiefly by the differences in the action exerted by them upon a ray of polarized light; such as dextroor ordinary tartaric acid, lavo-tartaric acid or ordinary tartaric acid, levo-tartaric acid para-tartaric or racemic acid, meso-tartaric acid, and meta-tartaric acid. It those of temperature, moisture, &c. It depends on the fact that a piece of carbon introduced into the course of an electric current offers a resistance to the passage of the current, which diminishes in a very marked degree in proportion to the amount of pressure exerted on the carbon. A small disc of carbon and another of vulcanite are held together between two platinum but-tons, which may be brought into connections, which may be brought into connection with a galvanic battery, and a strip of some substance like gelatine, which contracts and expands with great readiness, is so placed that by its variations in magnitude it varies the pressure on one of the platinum buttons and hence on the arbitance. platinum buttons, and hence on the carbon disc. The variations thus produced in the platinum buttons, and hence on the carbon disc. The variations thus produced in the force of the electric current are measured by a very delicate galvanometer, which is also placed in the circuit. So delicate is the instrument that the heat of the hand held a few inches off causes a deflection of the needle; while by a slight alteration in form the weight and vital heat of the minutest insect may be determined.

composed in good taste.

Consider the exact sense in which a work of art is said to be 'in good or had tarta'. It does not mean that it is true or false; that it is beautiful or ugly; but that it does or does not comply either with the laws of choice, which are enforced by certain mode laws of choice, which are enforced by a particular sort of education. It does not mean merely fashionable, that is, complying with a momentary caprice of the upper classes; but it means agreeing with the habitual sense which the most refined education common to those upper classes at the period gives to their whole mind.

Ruskin.

Teind (tend), n. [Icel. tiund, a tenth, and hence a tithe, from tiu, ten; Sw. tiende, Goth. taihunda, the tenth.] In Scotland, a tithe or tenth part paid from the produce of land or cattle. After the Reformation the whole teinds of Scotland were transferred to the crown, or to private individuals acceled titulars to whom they had been als called titulars, to whom they had been granted by the crown, or to feuers or renters granted by the crown, or to feuars or renters from the church, or to the original founding patrons, or to colleges or plous institutions. By a succession of decrees and enactments these tithes were generally rendered redeemable at a fixed valuation, but the clergy have now no right to the teinds beyond a suitable provision, called a stipend; so that teinds may now be described as that portion of the estates of the laity which is liable to be assessed for the stipend of the clergy of the Established Church. As a fund for the stipends of clergymen teinds are under the administration of the Court of Session.—

It is astonishing to see how rapidly a word is formed and takes root, if it expresses something of the so-called business of life. cise: succinct Telegraph (tel'e-graf), n. [Gr. tēle, far, at a distance, and graphō, to write.] 1. A general name for any instrument or apparatus for conveying intelligence beyond the limits of distance at which the voice is audible, the idea of speed being also im-plied. Thus the name used to be given to a semaphore or other signalling apparatus. The word, however, is now usually restricted in its application to the electric tele-graph, which from its power of rapidly conveying elaborate communications to the greatest distances has thrown all others into greatest distances has thrown all others into the shade. The electric telegraph, as com-prising the entire system of apparatus for transmitting intelligence by electricity, con-sists essentially (1) of a lattery or other source of electric power; (2) of a line-wire or conductor for conveying the electric cur-rent from one station to another; (3) of the rent from one station to another; (3) of the apparatus for transmitting, interrupting, and if necessary reversing the current at pleasure; and (4) of the indicator or signalling instrument. For the chief forms of battery in uso see under GALVANIC. The linewires for overhead lines are usually of fron, protected from atmospheric influence by galaxistic or by being vernished with boiled protected from atmospheric influence by galvanizing or by being varnished with boiled
linseed-oil, a coating of tar, or other means,
and are supported upon posts, to which
they are attached by insulators. (See InsuLATOR.) In underground lines the wires
are insulated by a gutta-percha or other
non-conducting covering, and inclosed in
iron or lead pipes. A description of the
line-conductor in submarine telegraphs will
be found under CABLE. The battery and
line-wire are common to all telegraphic systems; it is in the method of producing the
signals that the great variation exists; but in
all of them advantage has been taken of one all of them advantage has been taken of one or other of the three following properties of or other of the three following properties of the current: (1) its power of producing the deflection of a magnetic needle, as in the galvanometer (which see); (2) its power of temporarily magnetizing soft iron; and (3) its power of producing chemical decomposition. The needle-telegraph of Cooke and Wheatstone is an application of the first of these properties. In it a pair of needles is used, one of which, being magnetized, is placed within a multiplying coil, the other appearing on the dial of the instrument.

The plane of the coil is vertical; the needles hang on horizontal axes. The dial needle deflects its upper end to the right or left in accordance with the direction of the current, and it is by combinations of these deflections that the letters, &c., are formed. A double-needle telegraph, consisting of two single needle-instruments, has been used; but although it gives great increase of speed of transmission, from its expensiveness, requiring the maintenance of two systems of line-wires, it can never be popular. The needle-telegraph was never adopted out of England, and even here the Morse has been generally substituted for it. Its transmitting instrument is a reversing key, worked by a handle, which appears on the instrument below the dial-needle. The turning of this handle in one direction or the other gives rise to a current of electricity from the battery, which passes through the instruments of both receiver and sender. The attention of the receiver is called by the preliminary sounding of an electric bell. The electro-nagnetic instrument of Professor Morse is an application of the second of the above properties. By means of an electro-magnet, an armature which is attracted when the magnet is temporarily magnetized, a lever moved by the armature, and a style which noves with The plane of the coil is vertical; the needles hang on horizontal axes. The dial needle By means of an electro-magnet, an armature which is attracted when the magnet is temporarily magnetized, a lever moved by the armature, and a style which moves with the lever, this instrument impresses a message in dots and dashes on a ribbon of moving paper. (See Morse-Alphabet.) A modification of this instrument, called a sounder, in which the lever makes audible sounds by coming in contact with a brass rod, indicates the message by the length of the strokes produced. Frequently the Morse is simultaneously a recorder and sounder. It being necessary that this instrument should produce sharp and distinct impressions, and the current being weak for stages over 50 miles, a relay is added to it in the case of longer distances. (See RELAY.) The transmitting instrument is a lever, which, on being pressed, permits the current from the battery to flow into the line-wire during the time the contact is made. Both on account of its intrinsic merits and for the sake of uniformity the Morse is the most extensively used system, being that in use in America and on the Continent of Europe, and being also largely employed in Britain. Wheatstone's 'universal telegraph' is also in America and on the Continent of Europe, and being also largely employed in Britain. Wheatstone's 'universal telegraph' is also one in extensive use. The currents employed are magneto-electric, and are alternately positive and negative. They produce successive reversals of polarity in an electromagnet, which acts upon a light steel magnet and causes it to rotate through a large angle first in one direction and then in the capussite. Each of these rotations causes a net and causes it to rotate through a large angle first in one direction and then in the opposite. Each of these rotations causes a ratchet-wheel to advance one tooth, and this causes the pointer to advance one letter. At the same time the turning of the handle by which the currents are generated causes the pointer of the sending instrument to advance one letter for each current sont, so that the pointers at the two stations indicate the same letter. The same dial which serves for sending also serves for receiving. It is surrounded by a number of keys or buttons, and when any letter is to be sent its key is depressed, the operator continuing all the while to turn the handle for generating currents. The electro-chemical telegraph of Alexander Bain of Edinburgh takes advantage of the third of the above-mentioned properties of the current. Upon a metallic disc, which is carried round by clockwork, is laid a sheet of paper, prepared by having been dipped in a solution of prussiate of potass, nitric acid, and ammonia, over which rests a screw-plate, serving to guide a pen, or service in the consistent of a piece of fine steet connected. potass, nitric acid, and ammonia, over which rests a screw-plate, serving to guide a pen, consisting of a piece of fine steel, connected with the positive pole of the battery, the metallic disc being connected with the negative. The transmitting instrument is that of Morse. When a current is transmitted it decomposes the prussiate of potass in passing through the moistened paper, and the acid, uniting with the iron style at the positive electrode, forms ferrocyanide of iron or Prussian blue, leaving a distinct blue trace upon the paper moving under it. There are many more instruments, modifications of one or other of the above. Incations of one or other of the above. Instruments, as Hughes' telegraph, have been struments, as nugnes telegraph, have been invented which print the message in Roman characters, but as yet they have been little used. Autographic telegraphs, by which writing or a design can be produced in factsimile have also been invented, Casselli's telegraph effects this end by the use of s

non-conducting ink and Bain's chemical paper. Cowper's writing telegraph imitates hand-writing by a pen at the receiving station being made to follow the movements of a pen at the sending station. Two wires are necessary, one of them to produce similarity of position as regards left and right displacement, the other as regards up and down displacement. Strips of paper are drawn past both pens by clockwork. In addition to the delicate mirror or reflecting galvanometer (see GALVANOMETER), which Sir W. Thomson (Lord Kelvin) invented in connection with the Atlantic telegraph, the same electrician invented a self-recording instrument, consisting of a light coil of wire, very delicately suspended in a magnetic field, the motions of which coil, when a current is passed through it, non-conducting ink and Bain's chemical light coil of wire, very delicately suspended in a magnetic field, the motions of which coil, when a current is passed through it, are the means by which messages are recorded. The coil is attached to a very light glass siphon in the shape of an exceedingly fine capillary tube, through which ink from a reservoir is drawn by electric attraction, the reservoir and the moving paper ribbon upon which the ink falls being oppositely electrified. The extremity of the siphon is not in contact with, but only very near the paper. When there is no current the ink races a straight line; when the current is passing the marks or deviations constituting the letters are produced. The delicacy and rapidity of this instrument are even greater than those of the mirror galvanometer, and the siphon recorder accordingly is highly valued. Although the possibility of applying electricity to telegraphy was thought of in the latter half of the eighteenth century, the principal elements of success were wanting till the discoveries of the galvanic pile by Volta in 1800, and of electro-magnetism by Oersted in 1819, since which latter date the triumphs in electric elegraphy have been achieved. In Britain which latter date the triumphs in electric telegraphy have been achieved. In Britain the first public introduction of telegraphy was made in 1845, and thirteen years later the submarine cable between the Old and New Worlds was successfully laid. In 1872 Arew worlds was successfully laid. In 18/2 a really workable mode of sending simultaneously two messages in opposite directions on the same line was introduced, and it was also discovered that two messages could was also discovered that two messages could be sent in the same direction (duplex telegraphy). The two plans being combined formed quadruplex telegraphy, by which the message-carrying powers of the wires has been greatly multiplied. Wireless telegraphy has also been introduced.—2. A telegraphic message; a telegram. Trollope.

row snouts. They are confined to the oolitic division of the secondary rocks. **Teleostean**, **Teleost** (tel-e-osté-an, (tel'e-ost), n. A member of the order Teleostei ost), n. A member of the order Teleostei or bony fishes. Teleostean (tel-ē-os'tē-an), a. Of or pertain-

ing to the Teleostei.

Teleostean fishes (are) fishes of the kind familiar to us in the present day, having the skeleton usually completely ossified and the scales horny. Darwin.

completely ossified and the scales horny. Darwin. **Teleostel** (tel-ē-ios 'tō-i), n. pt. [Gr. teleos, teleos, complete, and osteon, a hone.] An order of fishes including the great majority of those having a well-ossified skeleton, and corresponding very nearly to Cuvier's osseous fishes. The order comprises almost all the common fishes, and includes the sub-orders Malacopteri, Acanthini, Acanthopteri, Plectognathi, and Lophobranchii. **Teleozoo** (tel'ē-ō-ō-on), n. [Gr. teleos

Teleozoon (tel'ē-ō-zō-on), n. [Gr. teleos, complete, and zōon, an animal.] Any animal

composed of a number of cells and arranged in tissues. H. Spencer.

Telepathic (tel-e-path'ik), a. Pertaining to

telepathy.

Telepathist (te-lep'a-thist), n. One who upholds the doctrine of telepathy.

Telepathy (te-lep'a-thi or tele-path-i), n.

[Gr. tele, far off, and pathos, feeling, as in sympathy.] The alleged phenomenon of the communication of feelings and impressions between persons at some distance without any agency other than that of mind:

without any agency other than that of mind; thought transference. **Telephone** (tel'é-fin), n. [Gr. têle, at a distance, and phônē, sound.] In a general sense any instrument or apparatus which transmits sound beyond its natural limits of andibility; thus the speaking-tube so much used in conveying the sound of the voice from one room to another in large buildings, or a stretched cord or wire attached ings, or a stretched cord or wire attached to vibrating membranes or discs, constitutes virtually a telephone. But the name is generally restricted to an instrument transiting sound by means of electricity and telegraph wires. About the year 1860 the idea that sound-producing vibrations could be transmitted through a wire by means of electricity began to be recognized by several men of science. Reis of Frankfort invented an apparatus which could reproduce at a distant station the pitch of a musical sound by means of a discontinuous current at a distant we have a discontinuous current along a telegraph wire. A great step in ad-vance was made in 1876 when Prof. Graham Bell, a Scotchman resident in America, dis-Bell, a Scotchman resident in America, dis-covered an articulating telephone which de-pends upon the principle of the undulating current, and by means of which the very quality of a note, and therefore conversation itself, could be reproduced at a distant sta-tion. Several varieties of telephonic appa-ratus are now in everyday use for inter-communication between distant places. The Bell telephone in its common form is shown in the accompanying cut. communication with the two terminals s s. One of the terminals communicates through a telegraph wire with one of the terminals of the coil of a precisely similar instrument at the other station, the remaining pair of terminals being connected through the earth, or through a return wire. Just in earth, or through a return wire. Just in front of the extremity of the magnet there is a thin plate of iron p, and in front of this again there is the mouth-piece of a speaking-tube o. By this last the sounds to be transmitted are collected and concentrated, and falling on the metal plate cause it to vibrate. These vibrations in their turn excite undulating electric currents which correspond exactly with the vibrations; that is, with lating electric currents which correspond exactly with the vibrations; that is, with the original sounds. The electric currents being transmitted to the receiving telephone cause corresponding vibrations in the plate or disc in it, and these reproduce to the ear the original sounds.

Telephone (tel²-fon), v.t. To transmit or

the ear the original sounds. **Telephone** (tel'e'foh), v.t. To transmit or reproduce, as sounds, speech, or the like, by means of the telephone. **Telephonic** (tel-e'fon'ik), a. Of or relating to the telephone; communicated by the telephone; as, a telephonic communication. **Telephonist** (telef'on-ist), n. A person versed in telephony, or who operates on the telephone. telephone

Telephotography (tel'é-fō-tog'ra-fl), n. The photography of distant objects. See preceding article.

Telerpeton (te-lèr'pō-ton), n. [Gr. tēle, far, and herpeton, alizard.] A lizard-like reptile, about 5 inches in length, found fossil in sandstones of the upper Trias near Elgin.

Telescope(tel'ō-skōp), n. [Gr. tēleskopos, farsecing, seeing afar, from tēle, at a distance, and skopeō, to view.] 1. An optical instrument essentially consisting of a set of lenses fixed in a tube or a number of sliding fixed in a tube or a number of sliding tubes, by which distant objects are brought tubes, by which distant objects are brought within the range of distinct, or more distinct vision. The law of action by which the telescope assists human vision is twofold, and that under all the varieties of its construction. A distant object viewed by the unaided eye is placed in the circumference of a large circle, having the eye for its centre, and consequently the angle under which it is seen is measured by the minute portion of the circumference which it occuries. Now when the distance is great, it portion of the circumference which it occupies. Now, when the distance is great, it
is found that this angle is too small to convey to the retine any sensible impression—
all the light proceeding from the object is
too weak to affect the optic nerve. This limit
to distinct vision results from the small
aperture or pupil of the eye. The telescope
substitutes its large object lens or reflector
for the human eye, and consequently receives a quantity of light proportioned to its

area or surface; hence a distant point, inappreciable by the eye alone, is rendered visible by the aid of the telescope. The rays of light, after transmission or reflection, converge to a point as they at first proceeded from a point, and thus an image of the object is formed which, when viewed by the eyejece or lens, is more or less magnified. The telescope therefore assists the eye in these two ways: it gathers up additional light, and it magnifies the object; that is to say, its image. The refracting telescope is constructed of lenses alone, which, by successive refractions, produce the desired effect. This instrument was formerly very cumbersome and inconvenient, inasmuch as its length had to be increased considerably with every accession of power; and though the substitution of achromatic for ordinary lenses has rendered it more portable, its construction even at the present day does not enable it to compete with the reflecting telescope as an astronomical investigator. The reflecting telescope is composed of specula or concave reflections and of the supplemental of the conceiver and the variety of the supplemental conceivers and the variety of area or surface; hence a distant point, inaptelescope is composed of specula or concave reflectors, aided by a refracting eye-piece. To this instrument we owe the most wondrous discoveries in astronomical science. The names of Newton, Gregory, Herschel, and Lord Posse are connected with its history. The following diagrams exhibit the principles of construction and action in both

sorts of telescopes. In fig.1, which illustrates the refracting telescope in its simplest form, A and B are two lenses of different focal lengths. Rays of light from a distant object falling upon the object glass A are converged to a focus at C. The eye-glass B, placed at its focal distance from the point of conat its focal distance from the point of convergence, gathers up the diverging rays and carries them parallel to the eye, magnifying the image formed at c. The magnifying power of the instrument is as AC:0B, or as the focal length of one lens to that of the other. In this construction the object is inverted by the intersection of the rays, and hence it is unsuitable for terrestrial purposes. To render the image erect a more complicated eye-piece, consisting of two additional lenses, is necessary. Fig. 2 shows

the structure of the reflecting telescope as constructed by Dr. Gregory. AB is a large speculum perforated in the centre; upon this fall the rays b, a and d, c, which are reflected to convergence at e. A smaller speculum, c, takes up the diverging rays and reflects them, slightly converging, through the aperture o, where they are received by a lens, and, after transmission, they intersect at x, and proceed to the eyeglass, whence they emerge parallel. The magnifying power of this instrument is great for the largeth being as $0^{6} e^{-\chi} \times C$ the structure of the reflecting telescope as for its length, being as $\frac{o \ e}{e \ C} \times \frac{x \ C}{x \ o}$. In the telescope invented by Sir Wm. Herschel

there is no second speculum, and no perforation in the centre of the larger one placed at the bottom of the tube. The latter is fixed in an inclined position so that the image formed by reflection falls near the lower side of the tube at its open end or mouth, where it is viewed directly by an the lower side of the tube at its open end or mouth, where it is viewed directly by an eye-piece without greatly interfering with the light. This arrangement, in the case of large reflectors, is imposed by their great weight and difficult management. Were it otherwise the ordinary construction would be preferred, the inclination of the speculum being a disadvantage. Chromatic aberrabe preferred, the inclination of the speculum being a disadvantage. Chromatic aberra-tion, which arises from the different refran-gibilities of the various coloured rays, and leads to the formation, by a lens, of a separ-ate image of a bright object for each coloured ray, is remedied by achromatizing the

lens, that is, by constructing it of two or more lenses of different kinds of glass, so that the colours, separated by one, shall be reunited by the others. See ACHROMATIC.—2. Same as Telescopium.—Prism telescope.
